# REVISION OF THE DEEP-WATER MOLLUSCA OF THE ATLANTIC COAST OF NORTH AMERICA, WITH DESCRIPTIONS OF NEW GENERA AND SPECIES. 

PART I.-BIVALVIA.

By Addison E. Verrill, Professor of Zoölogy in Tule Criversity and<br>Katharine J. Bush, Assistant in Prabody Museum of Tale Tnirersity.

This article is not intended as a review of all the known species found off our coasts. It is preliminary to a much more extensive report, in which full details of the distribution of all the species collected will be given, and for which the detailed tables have been prepared, giving every station for each species, with its position, depth, temperature, character of the bottom, ete.
Many of the larger and more prominent species were described and figured by the senior anthor several years ago in varions papers published in the Transactions of the Connecticut Academy and elsewhere. The smaller and more difficult species were put aside at that time, for more careful study, and are now presented.

The families that are most fully treated in this article are the Ledidre, Cuspidaridre, Diplodontidre, and Pectinidie. These inclute a very large number of deep-sea species in every region, and their species are often very difficult to distinguish without long and patient microseopic study and direct comparison of large series of specimens from various localities.

The present article is intended to give some of the results of studies of this kind, made during several years, of the large series of specimens dredged by the United States Fish Commission off our coasts from 1871 to 1857, together with those previonsly dredged by the senior anthor in the same region.

In order to avoid, so far as possible, the uncertainty necessarily connected with mere descriptions of these forms, we have had large camera-lncida figures made, as carefully as possible, not only of the new species, but also of some of those previously describerl from our coast, for comparison. It is, therefore, to be hoped that fatmre investigators may at least be able to understand the characters of the species now recognized by us, whether they agree with our determinations or not.

Although the collections studied are umsually extensive, and the number of stations represented is very large, it is noteworthy that a considerable number of species were met with but once, and sometimes only a single speeimen was obtained. This indicates that many additional species of such small deep-sea shells wonld be discovered in the same region if additional dredgings should be made.

Our investigations have enabled us to add to the fauna nine genera, four subgenera, and about eighty species and varieties, of which about seventy are deseribed as new species and seven as new varieties; of these, twelve species and one variety belong to the sonthern fana.

The following list shows the genera in which the new species and varieties are includerl. ${ }^{1}$ The new genera are printed in italic:

Martesiella, 1.
Abra, var. 1.
Macoma, 1
Montaenta, 4, var. 2.
Kelliopsis.
Cryptodon, 4, vir. 1.
Aximulns, 6.
Aximopsis, 1, var. 1.
Aximodon, 1.
Leptaximus, 1.
Cuspidaria, 8.
Cartiomya, 2.
Halonympha, 1.
Myonera, 3.

Poromyz, var. $1 . \quad$ Bathyarea, 2.
Cetoconch: 2. Bentharca.
Cetomya, $1 . \quad$ Limopsis, 2.
Lyousiella, 2. Solemya, 1.
Lyonsia, 1.
Clidiophora, 1.
Kennerlia. 1. Periplomis, 1. Limatula, 3. Chlamys, 2. Hyalopecten, 1. Camptonectes, 1. Cyclopecten, 2.

Nucula, 1, var. 1.
Leda, 1.
Ledellis, 1, var. 1.
Adranclla, 1.
Microyollia.
Yoldialla, 11, var. 1.
Malletia, 2.
Neilonella, 1.
Tindaria, 3.

No attempt has been made to give the complete synonymy and details of the distribution. Such matters have been reserved for the final report on the collections.

Unless otherwise stated, the station numbers are those of the United States Fish Commission and the serial mmbers are those of the United States National Museum.

The drawings, with few exceptions, were made by Mr. Alpheus $H$. Verrill, under the immediate supervision of the authors.

Peabody Museum of Yale University, New Hacen, Connecticut, Junuary 25, 189\%.

[^0]
## Family PHOLADID」E. <br> MARTESIELLA, new subgenus.

This subgeneric name is proposerl for the following species, which differs from Martesia in having a well-lefined, elongited, median, dorsal plate, posterior to the umbos, in addition to the shield-shaped one over them.

## MARTESIA (MARTESIELLA) FRAGILIS, new species.

(1'late LXXIX, fig. 10.)
Shell small, white, thin, fragile, wedge-shaped. The anterior end is very short and broadly romded, the aperture nearly elosed in onr largest specimen by a pair of callous plates. The antero dorsal margin is recurved toward the umbos, but not appressed, and forms a deep, spiral, open cavity. The valves have a very obtuse anterior emargination. A broad and moderately deep sulcus runs from the beak to the ventral margin; in front of this the surface is covered by thin concentric ribs, which curve downwand at the sulcus and form a distinct angle in line with the anterior emargination and corresponding with a slight ridge on the surface; these concentric ribs are crossed by fue radiating lines, which produce fine semations on their edges. Posterior to the sulcus the surface is marked only by irregular lines of growth, which, near it, take the form of more distinct grooves or ridges. The posterior end is prolonged, compressed, and bluntly romuded. The umbonal plate is thick, relatively largr, and usmally heart-shaped, with the posterior end broader and distinetly emanginate in the middle; the anterior end tapers somewhat and is blunt and angulated, or sometimes subacute. The posterior dorsal plate is long, narrow, and somewhat spatulate or clavate, and stands well in relief above the dorsal margin, with the edges free and the narrow anterior end rumning muler the posterior eud of the umbonal plate.

Length of one of the largest specimens, 7 mm ; height, 4.in mm.; thickness, 4 mm .

Young specimens 3 or 4 mm . in length are relatively shorter and thicker than the larger ones, but even these have the anterior callous pretty well developed; the umbonal plate is usually shield-shaped, the lateral borders emarginate, in contact with the most prominent part of the umbos; the posterior border is distinctly emarginate, and the anterior end has a central point or mucro, sometimes defined hy slightly concave posterior edges.

Many live specimens were fonnd in a piece of wood floating near station 2566, N. lat. $37 \circ 23^{\prime}$, W. long. $68^{\circ} S^{\prime}, 185^{\circ}$.

Family SEMELIDE.
ABRA LONGICALLIS (Scacchi), variety AMERICANA, new.
(Plate LXXXIII, figs. 6, 7.)
Abra longicallis Verrill, Trans. Conn. Acad., V1, pp. 224, 278, 1884.
Our specimens differ from the European form described and figured by G. O. Sars ${ }^{1}$ in having the posterior lateral tooth less remote and the cartilage-pit or chondrophore longer, the antero-dorsal margin more convex, and the whole shell relatively broader.

A very few specimens were obtained at six stations between N. lat. $39^{\circ} 49^{\prime}$, W. long. $68^{\circ} 28^{\prime} 30^{\prime \prime}$, and N. lat. $36^{\circ} 16^{\prime} 30^{\prime \prime}$, W. long. $68^{\circ} 21^{\prime}$, in 924 to 2,620 fathoms, 1883-1886.

## Family TELLINIDE.

## MACOMA INFLATA Dawson.

(Plates LXXVII, fig. 1; LXXXVIII, fig. 6.)
Macoma inflata (Stimpson MSS.) Dawson, Canadian Naturalist, VI, p. 377, 1872.-Terrill, Trans. Conn. Acaul., V, p. 568, 1882.

A number of live specimens and separate valves were obtained at six stations between N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ} 35^{\prime} 30^{\prime \prime}$, and N. lat. $40^{\circ}$ $3^{\prime}$, W. long. $70^{\circ} 31^{\prime}$, in 57 to 206 fathoms, 1877-1886. Murray Bay. Dawson. Gulf of St. Lawrence.-Coll. Whiteaves.

## Family PETRICOLID.Æ.

CHORISTODON ? CANCELLATUS Verrill.
(Plate XCVI, figs. 2, 3.)
Choristodon? cancellatus Verrili, Trans. Comn. Acad., VI, p. 435, 1885.—Dall, Bull. U. S. Nat. Mns., Nı. 37. p. 58, 1889.

One valva, station $2 \cup(6.5$, off Chesapeake Bay, in 70 fathoms, 1884.
Family KELLIELLID E .

## KELLIELLA NITIDA Verrill.

(Plates XCI, fig. 8; XCIII, fig. 10.)
Felliella sp. Vermill, Trans. Conn. Aead., VI, p. 279, 1884; Expl. Albatross, Report I'. S. Com. Fish and Fisheries for 1883, p. 576, 1885.
Kelliella nitide Verbill, Trans. Conn. Arall., VI, p. $438,1885$.
Comparatively fer specimens, at seven stations between N. lat. $390^{\circ}$ $5^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ} 44^{\prime} 30^{\prime \prime}$, and N. lat. $38^{\circ} 20^{\prime}$, W. long. $70^{\circ} 8^{\prime} 30^{\prime \prime}$, in 1,525 to 2,033 fathoms, 1883-1886.

[^1]Family LEPTONIIA or ERYCINID.E.

## KELLIA SUBORBICULARIS (Montagu).

(Plate XCIV, figs. 3, 4.)
hellia suborbicularis H. and A. Adams, Genera Recent Moll., II, p. 475: III, pJ. CXIN, figs. 8 a-c, 185̈.—.Jeffreys, Mritish Conchology, II, p. 225 , pl. v, fig. 3, 1863 ; V, p. 179. pl. xxxir, fig. 2, 1869.-Gocli, Rep. on Invert. of Mass., Binney's ed., p. 83, fig. 394, 1870.-Tryon, Amer. Mar. Conch., p. 171, j1. 32, figs. 433, 435, 1873.-G. O. Sais, Mollnsca Reg. Arcticib Norvegiar, p. 67, pl. 19, figs. $14 a-b$, 1878.-Jeffreys, Proc. Zö̈l. Soc., London, p. T00. June, 1881. - Smitn, E. A., Report Toy. Challenger, Zoïl. Lamellibranchiata, Nifi, p. 201, 1885.-Dalle, Bull. U. S. Nat. Mus., No. 37 , p. 200, pl. Lx vili, fig.5, 1889.

One fresh specimen, Massachusetts Bay, off' Salem, 1877. This species appears to be very rare on the American coast. In its hingecharacters it seems to agree closely with Bornia Philippi, 1836.

# MONTACUTA BIDENTATA (Montagu). 

(Plates XCIII, figs. 7, 8; XCIV, fig. 6.)
Mya bidentata Montagr', Test. Brit., p. 44, pl. xxvi, fig. 5, 1803.
Montacuta bidertata Forbes and Hanley, Hist. Brit. Moll., II, p. 75. pl. xviit, figs. 6, $6 a$.
Tellimya bidemtata M. and A. Adans. Genera Recent Moll., II, p. 478; III, pl. cxv, figs. 2.,2a, 1858.
Montacuta bidentata Jefriess, British Conchology, II, p. 208, pl. v, tig. 1, 1863;
 p. 69, pl. 19, figs. $17 a-b$, 1878.-Jeffreys, Iroc. Zoül. Soc.. London, p. 698, Jnne, 1881.-Verrill, Trans. Comn. Acad., V, p. 5 Ĩ1, 1882.-Busif, Trans. Conn. Acal., VI. p. 179, 1885; Expl. Albatross, Report IT. S. Com. Fish and Fisheries for 1883. p. 590.1885 Not Montacuta bidentata Gould.

Comparatively few specimens have been found in Long Island sonnd and at Thimble Island (A. E. Verrill); Provincetown, Massachasetts (S. I. Smith and O. Harger): Vineyard Sound, 1875; Cape Cod Bay, 1879; off Block Island. 1880; Woorls Hole, Massachusetts (Gut of Canso, and Naushon Gntters), 188こ-83. From low-water to 15. fathoms. Off Cape Hatteras, North Carolina, in 14 to 48 fathoms. 1883 and 1884.

MONTACUTA BIDENTATA (Montagu), variety TENUIS, new.
(Plate XCII, fig. 7.)
Shell similar to the typical M. bidentata in form and size, but relatively more elongated and more nearly elliptical, with the umbos and beaks somewhat less prominent. The surface is covered with fine and pretty regular lines of growth. The teeth in the right valve are strong, nearly equal in length and in the amount of divergence from the dorsal margin. They diverge more strongly and are thicker and more prominent, especially at the imer end, than is usual in the true bidentata.

Length of a medium size sperimen 4.7 mm ; height, 2.6 mm .

A few separate valves, off Cape Hatteras, North Carolina, in 16 to 17 fithoms, 1884.

MONTACUTA BIDENTATA (Montagu), variety FRAGILIS, new.
(Plate XCII, fig. 8.)
Shell snbelliptical, inequlateral, both ends broadly rounded, thin, fragile, covered with delicate lines of growth. The umbos are flattened; beaks but slightly prominent. The teeth in the right valve are smaller and more delicate than in the typical bidentutu, and diverge but slightly from the dorsal margin, as in that species.

Length, 4 mm . ; height, 3 mm .
One sperimen (No. 46134), station 816-17, in Narragansett Bay, in $8 \frac{1}{2}$ to 10 fathoms, 1850 .

## MONTACUTA STRIATULA, new species.

## (Plate NCIII, fig. 9.)

Shell rather large, thin and somewhat hyaline, compressed, broadelliptical with both ends well romeded, the anterior much the longer. Antero-dorsal margin nearly straight with a gradual slope; anterior end broadly and regularly rounded, its outline forming nearly the segment of a circle; ventral margin broadly and evenly convex; posterior end bhntly romded with its dorsal margin slightly concave and slop. ing rapidly. Umbos not swollen; beaks acute and only a little prominent. Surface covered with fine, regular, concentric, microscopic striar and more distant lines of growth. Interior somewhat shining with inconspicnous muscular scars. Hinge-margin thin, delicate, only slightly thickened. In the right valve there is, on each side of the beaks, a short, rather delicate, elevated, triangular tooth, terminating distally with an abrupt slope; these are nearly equal in size and length, the anterior one being slightly the shorter and more angular. They are separated by a $V$-shaped noteh, the sides of which form nearly a right angle. In the left valve there are two thin, slightly prominent elevations, scarcely worthy the name of teeth, separated by a rery wide angle under the beak.

Length of one of the largest specimens, 7 mm .; height, 6 mm .
This species is much larger than any of our other species of this gemns, and may possibly pove to be identical with $M$. bowmani, described and figured by Holmes. ${ }^{1}$ Owing, however, to the shortness of the description and small size of the fignres, this question camot be definitely decided without a careful comparison with authentic specimens.

A few separate valves were found off Cape Hatteras, North Carolina, in 15 to 48 fathoms, 1883-84.

[^2]
# MONTACUTA OVATA Jeffreys. 

(Plate NCII, figs. 9, 10.)
Tellimya ferruginosa Verrill, Notice of Recent Add. to Mar. Invert., Pt. 3, l'roc. U. S. Nat. Mus., III, p. 400, 1880.
Montacuta orata Jeffreys, Proc. Zoïl. Sor., London, p. 698. pl. Lxi, fig. 1 , June, 1881.-Verrill, Trans. Comn. Acad., V, p. 571, 1882; VI, p. 279, 1884.
A very few specimens, at fonr stations, off Newport. Rhode Island, and off Marthas Vineyard, in 100 to 157 fathoms, 1880-81.

## MONTACUTA TUMIDULA Jeffreys.

(Plates ACIII, fig. 6; XCIV, figs. 1, 2.)
Montacuta tumidula .Jeflereys, British Conchology, V, p. 177, pl. C. fig. 5, 1869.G. O. Sars, Mollusca Reg. Arctica Norvegire, p. 69, pl. 19, figs. 18 a-b. 1878.Verrill, Trans. Conn. Acad., VI, pp. 225, 279, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisherios for 1883 , p. 575, 1885.

One live specimen and three valves, at three stations between N. lat. $40^{\circ} 7^{\prime}$, W. long. $67^{\circ} 5 t^{\prime}$, and N. lat. $35^{\circ} 49^{\prime} 30^{\prime \prime}$, W. long. $74^{\circ} 34^{\prime} 45^{\prime \prime}$, in 843 to 1,091 fathoms, $1883-1886$.

## MONTACUTA CASTA, new species.

(Plate XCIV, fig. 5.)
Shell small, compressed, oblong-ovate, with the anterior end considerably the longer and both ends about equally rounded. Beaks small, scarcely rising above the margin. Surface covered with fine, regular, microseopic. coucentric strite and distant, raised lines of growth. The antero-dorsal margin is at first a little incurved, then slightly convex, with a gradual slope; the anterior end is obtusely rounded; the ventral margin is broadly and evenly ronuded; the posterior end is slightly produced and a little angulated below, in some specimens with the dorsal margin sloping more rapidly than the anterior and slightly incurved near the beaks. The hinge-margin is thin and delicate. In the right valve there are two moderately thick, rather prominent teeth; the one behind the beak is shorter than the other, with a more abrupt posterior slope; they are separated from the slightly thickened margin by a deep groove and from each other by a large notch or angle, the sides of which form an angle of about $90^{\circ}$. On the thickened margin there is a thin, rongh, shallow ligamentary furrow both in front of and behind the beaks. In the left valve there is an elongated, thin, and not very mominent, tooth-like elevation on each side of the beak; they are nearly equal in size and separated by a very broad angle.

Length of the largest specimen, abont 2.4 mm.; height, abont 1.8 mm .
A few separate valves, oft Cape Hatteras, North Carolina, in 14 to 17 fathoms, 1884.

## MONTACUTA CUNEATA, new species.

(Plates XCI, fig. 4; XCIII, fig. ㄱ.)
Shell small, elongated, wed ge-shaped, with a much prodnced, narrow anterior end, and with the dorsal margins nearly straight, sloping rapidly, and forming an obtuse angle at the beaks, which are decidedly behind the middle, prominent, curved inward. Anterodorsal margin sloping rapidly, at first nearly straight, becoming a little convex, and curving regularly into the ventral margin, thus forming a somewhat rostrated, narrow, evenly rounded anterior end; ventral margin nearly straight, sometimes witl a slight incurvature opposite the beaks; posterior end bluntly rounded, with its dorsal margin nearly straight, sloping about equally with the anterior. The surface is covered with fine, concentric, rather regular lines of growth and microscopic striations. Interior somewhat shining. In the right valve there are two well-detined, prominent, thickened teeth, separated by a large, leep notch under the beak; the anterior one is the larger and is broadly triangular, with a prominent exeurved tip, and is separated from the hinge-margin by a deep furrow, which runs obliquely within and below the thickened dorsal margin; the posterior one is set obliquely to the margin, from which it is separated by a well-defined groove. In the left valve there is a wide notch beneath the beak, with a rather inconspicuons, elongated, somewhat thickened anterior tooth-like projection, which continnes forward as a thickened imer margin nearly to the end, and a shorter, broad, triangular posterior projection. Color cream-white, sometimes tinged with piık.

Length of the largest specinen, about 3 mm.; height, 1.5 mm.
A few specimens were found off Cape Hatteras, North Carolina, in 15 and 16 fathoms, 1883-84.

## MONTACUTA TRIQUETRA, new species.

(Plate XCI, fig. 3.)
Shell small, covered with regular concentric grooves, scarcely compressed, somewhat triangular, with a slightly rostrated, angular posterior end, and a regularly rounded anterior one. Umbos a little swollen, beaks nearly central, nointed and a little prominent. The anterior and posterior corsal margins form nearly a riglit angle; the anterior margin is slightly convex and passes grarlually into the somewhat bluntly romuled anterior eud; ventral margin broadly convex, becoming slightly incurved toward the posterior rostration, which is wedgeshaped, rapidly tapered, witl a narrow truncate tip, defined below by a faint, radiating ridge; postero-lorsal margin is nearly straight, and slopes rapidly from the beaks. The surface is sculptured with strongly marked, smooth, rounderl, concentric ridges having the upper edge smooth and recurved; these are separated by deep, regular grooves
which appear in some places to extend beneath the upper edge of the ridges; on the umbos and posterior rostrum these ridges and grooves hecome feeble and irregular, like lines of growth. Internally the surface is white and smooth, with the miseular scars rather strongly marked.

The hinge-margin is rather thick; in the right valve there are two strong, prominent, curved, cardinal teeth, separated by a large, somewhat oblique notch which extends upward into the beak; the posterior tooth is the narrower and more prominent, with the tip curved forward and uprard; the anterior tooth is comected, just in front of the beak, by a bridge-like extension to the external margin, leaving between the tooth and the margin a deep submarginal groove; the imner edge of the hinge-margin is a little thickened to form a ridge continnous with the anterior tooth. In the left valve there is a distinct notch under the beak for the cartilage or resilium; in front of this is a prominent, tooth-like thickening of the margin of the shell, the proximal end of which becomes tooth like, but is continuons with the rest of the hingemargin; behind the notch there is no tooth and the margin is only a little thickened, without any special prominence.

Length, about 2 mm .; height, 1.4 mm .
Two valves, station 2307, off Cape Hatteras, North Carolina, in 43 fathoms, 1881.

## TELLIMYA FERRUGINOSA (Montagu).

## (Plate XC, figs. 7, 8.)

Tellimya ferruginosa H. and A. Adams, Genera Recent Moll.. II, p. 479, 1858.
Montacuta ferruginosa Jefrreys, British Conchology, II, p. 210, 1863; V', p. 178, pl. xxxi, fig. 9, 1869.
Tellimya ferruginosa G. O. Sars, Mollusca Reg. Aretice Norvegice, p. 70, pl. 20, figs. 1, a-c, 1878.- Yerrill, Trans. Conn. Acal., VI, 225, pl. xxx, fig. 13, 188.
Montacuta ferruyinosa Fischer, Manuel de Conchyliologie, p. 1027, tig. 775, 1887. Tellimya ferruginosa Dall., Bull. U. S. Nat. Mus., Nu. 37, p. 50, pl. xlv, fig. 13. 1889.
A few specimens were found at low-water at Woods Hole, Massachusetts (Gut of Uanso), and Gutters of Naushon Island, 1882-83. The figure of the living animal published by Verrill in 1884 has been copied by Dall, Fischer, and others. We now give additional ones.

## KELLIOPSIS, new genus.

## Type.-Montacuta eievata Stimpson.

The shell, in size and form, resembles Rellia and Montacuta. In both valves there is a small, prominent, anterior tooth and a low, elongated, thickened posterior ridge, seareely amounting to a tooth. The resilium is large and is attached to an elongated, oblique excavation on the proximal edge of the posterior tooth-like ridge, and also to a triangular pit beneath the beak; it bears a large, elongated, eurved ossicle. Soft parts not observed.

This genns appears to be closely allied to Montucuta, but differs in not having a definite, raised, posterior tooth; in having a large, elongated posterior cartilage, bearing a large ossicle attached to a special groove along a tooth-like ridge; and in having the structure of the linge in both valves nearly the same. In the position of the resilium it resembles Erycina, but the latter has two large teeth in both valves.

## KELLIOPSIS ELEVATA (Stimpson).

## (I'lates XCIII, figs. 2-4; XCIV, figs. 7, 8.)

> Montacuta bideutata Gouli, Rep. on luvert. of Mass., 1st ed., p. 59, 1841. (Not of Montagu.)
> Moutucuta clerata Stimpson, Shells of Now Eng., p. 16, 1851.
> Cyaminm eleratum II. and A. Adans, Genera lecent Moll., II, p. 477, 1858.
> Montachta eleruta Gocld, Rep. on Invert. of Mass., Binney's ed., p. 86, fig. 396, 18i0.-Tryon, Amer. Mar. Conch., p. 172, pl. xxxint, tig. 440, 1873.--Verrill, Report Invert. Anim, of Vineyard Sd., in 1st Rep. U.S. Fish Com., pl. 394, 68x, 1874 (auth. cop., p. 418).
> Tellimya elerata Dall, Bnll. U. S. Nat. Mus., No. 37, p. 50, pl. lxtiri, fig. 6 (as Moutacuta elevata Stimpson), 1889.

This rare species has been obtained at low-water mark, at Savin Rock, near New Haven, Comnecticut (J. E. Todd), 1871; Wellfleet, Massachusetts (Webster), 1879; Woods Hole, Massachusetts (Gut of Canso), 188: ; Naushon Island (Gutters and Sheep Pen Cove), 1882; and Narragansett Bay, in $8 \frac{1}{2}$ to 10 fathoms, 1880.

## Family DIPLODONTID A.

Ungulinide Fischer: Diplodontide + Cryptodontide Dall.

$$
\text { CRYPTODON Turton, } 1822 .
$$

## Type.-Cryptodon Alexuosus (Montagu).

The typical speciu's of this gemus have no distinct teeth in either valve, but the inner margin of the hinge-plate is more or less thickened or swollen in front of and behind the beaks. The ligament is posterior and lies in a long, enrved furrow in the midst of the marginal thickening; where it commences at the beak it is marginal and external, but as it runs backward it recedes from the edge and becomes more or less internal and invisible from the exterior. Moreover, the posterior end of the shell has one or more distinct radial corrugations or plieations to give the thin shell strength enough to resist the action of the large posterior adductor musele which is attached directly upon the principal plication. The perlal muscle is attached to the upper plication when the latter is present. Many writers have adopted the name of Axinus Sowerby, 1823 , for this genus; the latter name was given to a tertiary species, the structure of which is not fully determined. It may belong to a very distinct genns. Moreover, Turton's name seems to have actual priority of publication.

## CRYPTODON GRANDIS Verrill.

Cryptodon grandis Verrill, Trans. Conn. Acad., VI, p. 436, pl. xliv, fig. 22. 1885; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 575, 1885.Dalle, Bull. U. S. Nat. Mus., No. 37, p. 50, pl. xlvi, fig. 22, 1889.
Schizotharus grandis (pars) Locarid, Campagne du "Caudan," Annales de l’Université de Lyon, p. 180, 1896.

This large and interesting species, deseribed in detail and well figured in the first article quoted above, is a true Cryptodon, although very distinct from any of our other species. Therefore it seems strange that M. Locard has referred it to the very different genus, Schizotherus of Conrad, which belongs to the Mactride. He identifies without question a single valve, dredged by the Couden off the coast of France, in 1,710 meters, as our species. It is, therefore, doubtful whether his specimen is congeneric with ours, for the latter certainly las no affinity with Schizotherus.
One live specimen and a fer separate valves were dredged at three stations between N. lat. $38^{\circ} 29^{\prime}$, W. long. $73^{\circ} 9^{\prime}$, and N. lat. $35^{\circ} 9^{\prime} 50^{\prime \prime}$, W. long. $74^{\circ} 57^{\prime} 40^{\prime \prime}$, in 938 to 1,582 fathoms, 1883-84.

CRYPTODON INSIGNIS, new species.
(Plate XCI, figs. 1, 2.)
Cryptodon sarsii Verimill, Proc. U. S. Nat. Mns., III, 1. 399, 1880; Trans. Comn. Acad., TV, p. 570, 1882.
Shell mosually large and thick for the genus, opaque white or tinged faintly with reddish internally. Outline somewhat variable, usually broad-ovate or subquarlrate, usually moderately swollen, sometimes rather compressed. Umbos moderately large, not very prominent; beaks small and turned forward. Lumule cordate, rather large, pretty well defined. The radial folds and lobes are less marked than is usual in this geuns. A well-marked fold or shallow mudulation extends from the beak to the posterior margin, opposite the sear of the adductor muscle; anterior to this there is a broad, slightly raised ridge, extending from the umbo to the siphonal lobe of the margin; in front of this there is usnally a broad faint depression of the surface which is scarcely apparent in many specimens; a posterior groove runs close to and nearly parallel with the postero-dorsal margin. The antero-dorsal margin, in the lumular region, is straight or slightly incurved; the anterior end is short, a little prominent below the lumule, and obtusely rounded; the ventral margin, is very broadly rounded, usually with a slightly more prominent lobe at or just behind the middle, with at more decided but obtuse projection (siphonal lobe) farther baek where it joins the posterior margin, which is usually somewhat incurved, corresponding to the external wave-like depression, becoming convex opposite the posterior external fold; the postero-dorsal margin slopes rapidly from the beak and is sometimes broadly rounded, and at others slightly convex. The surface is covered with conspicuous, more or less irregular, Proc. N. M. vol. xx- 50
rounded, obtuse, often prominent lines of growth with a thin yellowish brown epidermis which, under the lens, is closely covered with minute granules often arranged in more or less distinct concentric lines. The posterior hinge-margin is somewhat thickened, the ligamental groove is long and curved, diverging considerably from the margin of the shell at its posterior end and exteuding forward under the beak. Muscular scars and pallial line in the largest specimens strongly narked; the anterior scar is considerably elongated and has a number of lobes or seallops on its inner margin.

Length of a medium-sized specimen, 27 mm ; height from siphonal lobe to beak, 27 mm .; brealth, 14 mm . Length of a larger, more ovate specimen, 32 mm . ; height from siphonal lobe to beak, 35 mm .; breadth, 21 mm.

This speeies presents considerable variation in ontline and in the degree of convexity of the valves; some are subquadrate in form, others subcordate, and others pretty well rounded, but the majority are oblong-obvate with a posterior truncation, corresponding to the broad radial groove; some of the valves are considerably inflated, but most of them are more compressed than is usual in this genus. There is also considerable variation in the prominence of the siphonal lobe and broad radial ridge, and in the size of the lines of growth, which in some specimens are quite fine and regular, and in others mevenly developed, those on the anterior part appearing almost like concentric ribs.

Many separate valves, at four stations between N. lat. $44^{\circ} 54^{\prime}$, W. long. $599^{\circ} 46^{\prime} 45^{\prime \prime}$, and N. lat. $42 \circ 19^{\prime}$, W. long. $690472^{\prime}$, in 65 to 47 fathoms, 1879 and 1855.

The single valve fom off Cape Cod, 1879, and identitied as Cryptodon sarsii, proves to be the young of this species.

CRYPTODON PLICATUS Verrill.
(Plate LXXXIX, fig. 6.)
Crypitodon plicatus Verrill, Trans. Conn. Acad., VI, pp. 437, 450, 1885.
One young live specimen and one imperfect valve of this characteristic and fragile species were found at two stations, off Martlas Vineyard, in 1,073 to 1,122 fathoms, 1854 .

CRYPTODON CROULINENSIS (Jeffreys) Smith.

> (Plate XC, figs. 3, 4.)

Clausina cromlinensis .Jeffreys, Ann. Mag. Nat. Hist., XX, p. 19, 184.
Axinus cromlinensis Jeffreys, Brit. Con., II, p. 250, 1864.-G. O. Sars, Mollnsea Reg. Arcticie Norvegiæ, p. 62, pl. 19, figs. 8, a-b, 1878.—Jeffreys, Proc. Zoül. soc., London, p. 703, June, 1881.
Cryptodon cromlinensis Smiti, E. A., Report Voy. Challenger; Zoül. Lamellilranchiata, XIII, p. 193, 1885.
Shell small, obliquely subovate, with the beaks prominent, and the anterior end considerably the longer. The anterodorsal margin is
nearly straight, sloping rapidly from the beak: the anterior end is distinctly produced, erenly rounded; the ventral margin is slightly but regularly convex to the lower posterior fold; the posterior end is marked by two distinct plications separated by a rather prominent ridge which, at the margin, appears as a rounded projection separating two reentrant curves; the postero-rlonsal margin is conrex, sloping rapidly to the upper plication. The ligamental area is relatively large, long, elliptical, defined by a distinet groove. Internally the hingemargin is considerably thickened, especially direetly muder the beak, where there is a slight swelling; the posterior ligament ocenpies a very distinct groove, and extends forward under the tip of the beak.

Length, 3.5 mm ; height, 3.7 m mm .
The shell here referred to this species appears to agree well with the figures and descriptions given by G. O. Sars. It pretty elosely resembles some varicties of $C$. gouldii. The principal differences externally are in the somewhat more produced anterior end and the longer and straighter antero-dorsal margin; the posterior plications are also less strongly developed.

Found in small numbers at about thirty stations north of Cape Cod, between N. lat. $43^{\circ} 442^{\prime}$, W. loug. $69 \supset \because^{2}$, and N. lat. $4 \because^{\circ} 30^{\prime}$, W. long. $70^{\circ} 35^{\prime}$, in 13 to 73 fathoms, 1573-1879.

CRYPTODON CROULINENSIS (Jeffreys) Smith, variety ALTUS, new.
(Plate LXXXVIII, figs. 1, ๗.)
Shell higher than long, larger than the rommon form. Umbos prominent, elevated and turned forward, so as to leave a rather large, conspicuous, flattened, lumbar area, which is bordered externally by a slight ridge, followed by a concave depression in the surface, which forms a slight indentation in the anterior margin, and resembles the posterior phication, but is more shallow. The antero-dorsal margin in the lumar region is slightly concave, but slopes very rapidly; the anterior end is a little more prodnced than the posterior, but both are decidedly short; the rentral margin is pretty evenly rounded; posteriorly there are two distinct plications; the lower or larger one is moderately sumken and extents from the beak to the posterior margin, the upper one is much shorter and narrower and defines the narrow, lanceolate, ligamental area; each produces a decided indentation in the margin, that caused by the lower one being more sharply defined and shorter than the other, these are separated by a well-defined, curved, radiating ridge which extends a little below the margin; the postero-dorsal margiu is strongly convex, evenly rounded, with a rapid slope; the hinge margin is considerably thickened, especially beneath the beak, and in the right valve forms a distinctly raised tubercle.

Length, 5 mm . ; height, 6 mm . Eastport, Maine, 1870.
Another specimeu, from station 292 , is slightly smaller. Length,
4.5 mm . ; height, 5.25 mm . In this the anterior or upper plieation is much less distinct than in the type, and it is therefore possible that this feature is abnormal.

## CRYPTODON EQUALIS, new species.

(Plate XCI, figs. 5, 6.)
Shell of moderate size, grayish white, rather swollen, pyriform, usually a little higher than long, but sometimes the height and length are about equal. Umbos rather prominent; beaks median, conspicuously raised above the margin and enrved strongly forward so as to produce a rather deep, broad, cordate, but ill defined lmular area. Anterior and posterior ends nearly equal. The dorsal margin slopes rapidly on both sides of the beak; anteriorly, in the lmular region, it is nearly straight; the anterior end is pretty evenly rounded, forming a continuous curve with the ventral margin, which forms nearly a semicircular curve; the posterior end has one broad, shallow undulation which causes a slight incurvature in the postero-ventral margin; above this the dorsal margin is very slightly convex and forms an angle at the commencement of the fold. The ligamental area is marked by a smooth, long, lanceolate, slightly sunken portion, clearly separated by an incised line. The general surface is covered with slightly marked, more or less irregular lines of growth. The hinge-margin is moderately thickened and is essentially the same in both valves. There is a well marked swelling both before and behind the beak and a more conspicuous one immediately under it; a less conspicnous thickening, with its external edge excurved, extends along the postero-dorsal margin, in the ligamental region. Musenlar and pallial scars indistinct.

Length, 5 mm .; height, $5 \frac{1}{2} \mathrm{~mm}$.; thiekness, 4 mm . Some specimens are somewhat lasger than this.

In the large series which we have of this species there is some variation. In some cases the form is less swollen, the length is slightly in excess of the height, so that the general ontline is more evenly rounded. The species is, however, notable for the equality of the anterior and posterior ends and the presence of the single slight undulation. Cryptodon gouldii somewhat resembles this species, but differs in being longer in proportion to its height, in its more compressed form, and in having two distinct folds or undulations. It is also closely allied to C. flexuosus of Europe, but is more pyriform in shape and lacks the anterior angulation noticeable in that species.

Taken at thirty-two stations, between N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ} 35^{\prime}$ $30^{\prime \prime}$, and N. lat. $37^{\circ} 08^{\prime}$, W. Fong. if $33^{\prime}$, in 94 to 1,537 fathoms, $1873-$ 1886.

CRYPTODON PLANUS, new species.
(Plate LXXXVIII, figs. 3, 4.)
Shell small, well-rounded, the length and height about equal, with the beak small, prominent, nearly central, curved strongly forward,
forming a small, smiken, heart-shaped, lunular area. Posteriorly there is only a faint, depressed undulation, which causes but a slight indentation or angulation in the margin; behind this the surface rises slightly and forms an inconspicuous ridge surrounding the ligamental area, which is long, rather marrow, and sunken, so that its margin is scarcely visible in a side view. The dorsal margin is a little convex and slopes but little, and about equally on both sides of the beak; the anterior end is well-rombled and slightly produced; the ventral margin is broadly rounded, a little produced in the middle, and nearly straight or very slightly incurved posterionly, opposite the undulation; behind this there is a slight obtuse angulation corresponding to the ridge below the ligamental area. Surface dull grayish white. The hinge-margin is considerabiy thickened, especially below the beaks and lumur area, and a thickened ridge also extends backward beyond the ligamental area. There is no distinct tubercle nor tooth like projection. The posterior ligament is unusually strong, and oceupies a rather conspicuous submarginal groove which runs forward under the beak as a thin incised line.

Length, 4 mm.; height, the same.
Found in 8 to 100 fathoms, north of Cape Cod, in the Gulf of Maine, Casco Bay, Bay of Fundy, and Halifax Harbor, 1872-1585.

## CRYPTODON OBSOLETUS, new species.

(Plate LXXXIX, figs. 1, 2.)
Shell small, higher than loug, with the ends and ventral margin rounded. Umbos somewhat prominent and swollen; beaks curved strongly forward. Posterior plication obsolete, or nearly so, only visible in certain positions, and imperfectly defined by a faint undulation of the surface and margin. The anterodorsal margin is slightly convex in the lumular area, and slopes rapidly to the broadly rounded anterior margin with which it forms a very slight and very obtuse angle; the whole ventral margin is well-rounded, a little prodnced in the middle; the posterodorsal margin is broadly convex and ends distally in a very obtuse, rombded angle, above which there is a slight inbending of the edge. The hinge-plate is rather thick, especially posteriorly. The ligament is rather strong and considerably curved and occupies a narrow, but very distinct groove, mostly within the margin posteriorly, and extends forward under and in front of the beaks. The anterior hinge-margin is thickened and a little flexnons toward the anterior angle of the shell; the proximal end, just under the beak, is slightly thickened withont forming any apparent tooth. Under the microscope, the surface is covered with rather coarse, irregular, concentric undulations, and fine, raised lines of growth, becoming smoother at each end, where there are patches of a closely adherent coating of red mud and iron oxide.

Length, 2.4 mm. ; height, 2.6 mm .

Fomr specimens, at three stations, ofi Marthas Vineyard, in 100 to 390 fathoms, 1880-1885.

## AXINULUS, new subgenus or genus

Type.-Aximulus brevis, new species.
We propose this division to include those speries which agree with Cryptodon in the character of the hinge and ligament, but lack the plications of the shell, and have, therefore, a smaller posterior adductor muscle.

CRYPTODON (AXINULUS) BREVIS, new species
(Plate LXXXIX, figs. 7. 8.)
Shell small, short, the height exceeding the length, somewhat pyriform, with slightly prominent umbos and small subcentral beaks, which are but little prominent and turn forward. The antero and posterodorsal margins are abont equal in length, the latter slightly more broadly rommed than the former, which is a little incurved near the beak so as to form a very slight lumbar area; both ends are broadly romnded and nearly equal; the ventral margin is slightly eonvex and a little produced just in front of the middle; an exceedingly faint, scarcely discernible mululation rins from the beak to the posterior ventral margin. The surface is covered with very fine, close, parallel lines of growth visible only when much magnitied. Grains of fine ferruginous sand or iund usually adhere closely to the surface, both anteriorly and posteriorly. The posterior ligament is well-developed and occupies a well-marked marginal groove; a small, thickencd, more internal portion, situated just behind the beak, within the margin, appears to be continnous with the external ligament. The inner edge of the dorsal margin is slightly thickened, for a short distance, just in front of the beak.

Length, $2 \frac{1}{3} \mathrm{~mm}$. ; height, 2.5 mm .
Several live specimens and separate valves were found at six stations, between N. lat. $40^{\circ} 16^{\prime} 50^{\prime \prime}$, W. long. $67^{\circ} 5^{\prime} 15^{\prime \prime}$, aud N. lat. $38^{\circ}$ $22^{\prime \prime}$, W. long. $70^{\circ} 15^{\prime} 30^{\prime \prime}$, in 984 to $1,5: 5$ fathoms, $1833-1886$.

At station 2208 was fonnd a single imperfect valve closely resembling this species but of much larger size.

Length, 5.5 mm .; lieight, 6.5 mm .
It is, however, much less regular in outline, having a nearly straight, rapidly sloping antero dorsal margin, merging very abruptly into the broadly and very slightly enrved and sloping anterior margin, forming a somewhat angolar and little produced anterior end; ventral margin strongly eonvex, eurving gradually into the posterior margin which slopes rapidly from the beak; postero-dorsal margin is eonvex but rises only a little above the outline of the distinct ridge which borders the ligamental area.

CRYPTODON (AXINULUS) INEQUALIS, new species.
(Plate NC, figs. 1, 2.)
Shell small, somewhat oblong, with the anterior end much the longer. Umbos rather prominent, beaks elevated, curved strongly forwarl, so as to leave a small, deep lumular area. The antero-dorsal margin is at first nearly straight, sloping bnt little, and is nearly parallel with the ventral margin; the anterior end is produced. broadly and evenly romded: the rentral margin is much less rounded, with the midile portion almost straight for a short distance, toward the posterior end it is subtruncate and slightly angulated; the postero-dorsal margin is convex and slopes rapidly; a very slight depression runs from the beak to the postero-ventral margin, but is so slight as to be scarcely worthy the name of plication or fold; posterior to this there is a distinct snbmarginal ridge separated by a rather deep groove, from the ligamental area, which is long and narrow. The surface appears to the naked eye nearly smooth, bluish white; muler the microscope it is marked by slight, raised, concentric ridges and faint undulations, which are the most regnlar and distinct on the mombos. In addition to these the whole surface, when highly magnified, has a fine fibrous appearance; on some parts there are remnants of a thin, pale yellowish epidermis. The hinge-margin is distinctly thickened, with a slight protuberance directly under the beak, where it is thicker than elsewhere. The posterior ligament is rather large aud strong, and occupies a conspicnons groore extending from under the beak about onethird the length of the postero dorsal margin.

Length, 4.5 mm . ; height, 4.2 m mm. ; thickness, about 4 mm .
A few specimens have been found in 14 to 49 fathoms, at about eleven stations north of Cape Cod, in Casco Bay, and in Halifax Harbor, 1873-1879.

CRYPTODON (AXINULUS) SIMPLEX, new species.

> (Plate XCII, figs. 3, 4.)

Shell small, thin, fragile, translucent bluish white, somewhat inflated, nearly circular in outline and withont any posterior undulations. Beaks small, acute, slightly prominent, turned forward. Antero-dorsal margin excavated in front of the beaks and convex farther forward; anterior margin broadly and evenly rounded and, with the ventral margin, forms nearly a circular curve: the posterior margin similarly rounded, but slightly tlattened in the middle; postero-dorsal margin broadly convex without any distinct angulation posteriorly. The surface is nearly smooth and somewhat glossy on the umbos; it is marked by rather indistinct, small, concentric waves or undulations and microscopic lines of growth. Interior somewhat shining. The hinge-margin is thin, delicate, and very simple, with but a very slight thickening in the region of the beak; a narrow groove for the ligament is visible just
before and behind the beaks, but there is no tooth-like prominence at any point.

Length, about 3.1 mm. ; height, about 3 mm .
Oue imperfect specimen, station 1093 , N. lat. $39^{\circ} 56^{\prime}$, W. long. $69^{\circ}$ $45^{\prime}$, in 349 fathoms, 1882.

This species is remarkable for the plainness of its surface, and the simplicity of its hinge, as it has neither radial undulations nor toothlike projections on the hinge-margin. In form it greatly resembles Axinopsis orbiculatu, but lacks the couspicuous concavity in the anterodorsal margin. It has, however, a very obvious posterior ligamental furrow in the same relative position as that of other species of Cryptorton.

A single valve taken at Eastport, Maine, 1872, agrees closely with the type in form, but is somewhat less thin and hyaline aud the beaks are a tritle more prominent. The surface has faint and rather distant concentric undulations, visible only under the microscope, being most distinct on the umbo. The microscopic striations are a little more distinet and in some lights give to the surface a fibrons or finely vermiculate appearance when highly magnified. This character, however, has been noticed in other species. The hinge-margin is a little more thickened and has a minute swelling on the inner margin just beneath the beak, scarcely worthy the name of tooth; the ligamental groove is also somewhat more strongly marked. This may prove to be a distinct species more nearly related to Axinopsis orbiculata from which it differs in having the antero-dorsal margin convex instead of strongly concave, and the gencral outline more evenly rounderl, aud a less evident toothlike thickening of the hinge-margin.

Leugth, about 2.8 mm .; height, about 2.6 mm .

## CRYPTODON (AXINULUS) PYGMÆUS, new species.

(Plate LXXXVI, figs. 3, 4.)
Shell minute, somewhat compressed, transversely ovate, inequilateral, with the anterior end the longer, and with a slightly produced posterior angnlation. Surface scarcely lustrons, covered with fine lines of growth and microscopic striations, and more or less iucrusted with ferruginous mud, especially posteriorly; there is barely a trace of ${ }^{\prime}$ a posterior fold. Umbos a little prominent, beaks small, slightly raised above the margin, and turned a little forward. The anterodorsal margin is nearly straight, or sometimes slightly convex, with a slightly excavated, small, lumlar area; the anterior end is broad, considerably produced, and evenly rounded; the ventral margin is broadly rombded, not at all produced, and joins the posterior margin in a small obtuse angulation, above which the dorsal margin is slightly convex and slopes rapidly from the beaks.

The inner surface is smooth with inconspicnons muscular scars.

The hinge-margin in the right valve is slightly thickened with a distinct, tootn-like prominence below and slightly in front of the center of the beak, and an inner fold like thickeuing of the posterior margin to support the ligament; in front of the lunular area the margin is convex and slightly everted.

Length, about 1.6 mm. ; height, about 1.4 mm .
A few live specimens were fond at three stations between N. lat. $47^{\circ}$ $40^{\prime}$, W. long. $47^{\circ} 35^{\prime} 30^{\prime \prime}$, and N. lat. $39^{\circ} 54^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ} 20^{\prime}$, in 206 to 499 fathoms, 1883-1886.

This species is allied to C. ferruginosus (Forbes), from which it differs in its distinctly produced and angulated posterior end, and longer or more produced, evenly rounded anterior end. It also has cousiderable resemblance in form to C. tortuosus Jeffreys, but that has a very lustrous surface and more vitreous texture, and moreover entirely lacks the posterior angulation.
C. suboratus of Jeffreys, seems to resemble rather elosely the small specimens of this species, but that has more prominent beaks, is wedge-siaped, the antero-dorsal margin sloping pretty rapidly from the beak, instead of being nearly straight and horizontal as in our species.

CRYPTODON (AXINULUS) FERRUGINOSUS (Forbes).

## (Plate LXXXYII, figs. 7, 8.)

Cryptodon ferruginosus Yerrill, 'Trans. Comm. Acad., V, p. 570,1882 ; VI, p. 279, 188t; Expl. Albatross, Report U. S. Com. Fishand Fisheries for 1883, p. 575, 1885.-Dall, Bull. U. S. Nit. Mus., No. 37, p. 50, 1889.

Aximus ferruginosus Locard, Campagne du Caudan, Annales de l'Universitŕ de Lyon, p. 191, $1 \times 96$.
This very common species was found at mumerous stations from N . lat. $42^{\circ} \circ 47^{\prime}$, W. long. $61 \circ 04^{\prime}$, to N. lat. $3 J^{\circ} 12^{\prime} 10^{\prime \prime}$, W. long. $74^{\circ} 57^{\prime} 15^{\prime \prime}$, in $125 \frac{1}{2}$ to 1,525 fathoms, $1880-1886$.

CRYPTODON (AXINULUS) OVATUS, new species.
(Plates NCI, fig. 7; NCIII, fig. 1.)
Shell small, ovate, not swolleu, with the posterior end produced and somewhat pointed, rusty brown in color and heavily incrusted with iron oxide. Umbos rather flattened; beaks small and concealed by the coating of ferruginous matter. The anterior eud is well-rounded with a nearly semicircular curve; the ventral margin is broadly convex; the posterior margin is tapered and produced at the end, with the dorsal margin a little convex and sloping rapidly. The hinge-margin is a little thickened and much obscured by the incrustation. In the left valve there is a rather prominent, blunt, tooth-like swelling below the lunular area; in the right valve there is a corresponding notch and a rather wide ligamental furrow commencing beneath the beak, and running back subparallel with the dorsal margin, becoming more
internal posteriorly. Just beneath the beak is an elongated tooth-like thickening of the inner margin which consequently emres downward at this point. Muscular scars whitish, ineonspicuous. The external surface, so far as visible, seems to be smoothish with irregular lines of growth.

Length, 1.6 mm .; height, 1.4 mm .
Two valces, station 949, N. lat. $40^{\circ}: 3^{\prime}$, W. long. $70^{\circ} 31^{\prime}$, in 100 fathoms, 1881. This species is encrusted very much as Cryptodon (Aximulus) ferruginosus, but is quite different in its much more strongly developed hinge and ovate form.

From station $2113, N$ lat. $35^{\circ} 20^{\prime} 30^{\prime \prime}$, W. long. $75^{\circ} 19^{\prime}$, in 15 fathoms, there are three sperimens (No. 35531) of considerably larger size which agree closely with this species and are probably ikentical. They are more extensively enerusted with ferruginons mud aud are somewhat higher in proportion to their length; the ventral margin being slightly produced in the middle, bnt they have the same posterior augulation and the same erenly produced anterior end. The beaks are larger, romded, and relatively more prominent above the margin. 'The lingemargin is very thin and delicate, but does not differ essentially in other respects from the smaller specimens.

Length, 2.6 mm. ; height, 2.2 mm.

## AXINOPSIS ORBICULATA G. O. Sars, variety INEQUALIS, new.

(Plate X('II, figs. in, 6.)

> Axinopsis orbiculatu G. O. Sabs, Mollusca Reg. Arcticer Norvegiar, p. 63, pl. 19, ligs. 11a-n, 1878.-Verbill, Trahs. Comi. Acarl., V', p. 569, 1882.-Bush, l'roc. U. S. Nat. Mus., VI, p. 243, pl. ix, fig. 4, 1883.

The mmerous specimens of this species show considerable variation in form and character of the hinge. Many specimens show the cardinal tooth and pit as described and figured by (i. O. Sars; others have the hinge-margin nearly smooth or with mere rudiments of a tooth and pit. Our specimens moreover show a thin, contimons external ligament, which should be lacking according to Sars' description, but he may have overlooked it. In form many of onr specimens are evenly rounded, as tigured by Sars, but others have the antero-dorsal margin more concave and the anterior end somewhat produce.l, while the postero-dorsal margin is somewhat straighter than usual.

Specimens from the Bay of Fundy hare a somewhat oblong form, with the ventral margin more nearly straight or but slightly convex, and with the anterior end distinctly produced. This form seems suffi ciently distinct to receive a varietal name, and we therefore propose to call it variety inequalis.

## AXINOPSIS CORDATA, new species.

$$
\text { (Plate XCVII, figs. } 5,6 . \text { ) }
$$

Shell small, white, smoothish, rounded or somewhat cordate, longer anteriorly, with small, little prominent heaks curving forward. Anterodorsal margin a little convex, sloping gradnally and passing somewhat abruptly into the anterior margin, which is broadly and ohtusely rounded; ventral margin strongly convex, somewhat produced in the middle; posterior margin pretty evenly rounded, except in the middle, where there is a slightly produced portion corresponding to the plication; postero-dorsal margin strongly convex in the middle. The surface is marked by fine, microscopic, concentric stria and irregular lines of crowth which, on the umbo, appear as slight undulations. The ligamental area is relatively large, prominent in the middle, and defined by a distinct groore, beyond which there is a well marked but low radiating rifge or plication which forms an incouspicuous projection at the margin; anterior to this there is a very slight wave-like depression of the surface, much as in most species of Cryptodon. The hinge-margin is decidedly thickened; in both valves there is a rather large, obtuse tooth just below the beak, from which it separated by a rather large space for the ligament which runs backward for a short distance in a conspicuons submarginal groove, becoming internal distally; interiorly the groove is narrow and ontside the margin.

Length, about 2 mm . ; height, the same.
This species is refered to the genms drimopsis with some donbt, although it has the distinct cardinal tooth and ligament-groove. It has, however, a single posterior plication similar to that seen in some species of Cryptodon; but the character of the plications vary in that genus, in some cases being very strong and in others obsolete or nearly so. In fact, the genus Axinopsis can hardly be distinguished from it except by the distinctly developed cardinal tootl, which is only partially differentiated from the proximal end of the anterior hinge-plate.

A few separate valves and two live young were found at six stations between N. lat. $40^{\circ}$, W. long. $71^{\circ} 14^{\prime} 30^{\prime \prime}$, and N. lat. $35^{\circ} 4 \ddot{ }^{\prime \prime}$, W. long. $74^{\circ} 54^{\prime} 30^{\prime \prime}$, in 43 to 202 fathoms, $1880-1884$.

The young specimens fiom stations 570 and 943 are referred to this - pecies with considerable doubt, as they have a much more rounded outline, although the hinge-magin is similar.

AXINODON, nevv genus.
Type.-Axinoton ellipticus, new speeies.
Shell thin, rounded or ovate, withont plications. Hinge with one or two small or subrudimentary teeth. Ligament internymphal, posteriorly so far internal that its inner end, distally, is attached below the inner edge of the hinge-plate, and therefore covers its entire breadth.

AXINODON ELLIPTICUS, new species.
(Plates XC, figs. 5, 6; XCII, fig. 1.)
Shell small, nearly smooth, swollen, transversely elliptical and somewhat oblong, with rather prominent mobos and with the beaks considerably behind the middle and curved forward. The antero-dorsal margin is decidedly convex and somewhat excurved, the anterior end is longer and a little broader than the posterior ; both are nearly evenly ronnded; the ventral margin is broadly romuded and nearly straight for a short distance along the middle; the postero-dorsal margin is convex and merges into the posterior end in a regular corve. The lumar area is rather distinct, but withont any very definite boundary. The surface is nearly smooth, covered only with tine, close lines of growth, which, under the microscope, appear as delicate, raised lines, separated by grooves of abont the same width; this sculpture is very regular over most of the surface, but on the umbos some of the ridges are so large as to appear like small mudulations. The interior surface is smooth and white; the muscular scars are indistinct ; the hinge-margin is rather thin; the posterior ligament is prominent, wedge-shaped, widest distally, and oceupies a distinct groove covering the whole breadth and extending abont one-third the length of the postero-dorsal margin and rumning forward mender the beaks. In the left valve there are two slightly raised, minute, obsenre, romnded teeth under the beak, of which the anterior is a little more distinct than the other; farther forward, and separated from the latter by a slight noteh, there is an elongated thickening of the margin forming a sort of lateral tooth or lamina and separated from the onter edge by a narrow groove. In the right valve the anterior tooth-like thickening is less distinct and there is only a very slight rounded swelling of the lunular margin muder the beak.

Length, 3.5 mm .; height, 3 mm .
Two live specimens (No. 35175), station 2096, N. lat. $39^{\circ} 22^{\prime} 20^{\prime \prime}$, W. long. $70^{\circ} 52^{\prime} 20^{\prime \prime}$, in 1,451 fathoms, 1883.

## LEPTAXINUS, new genus.

Type-Leptaxinus mimutus, new species.
Shell small, short-ovate, inequilateral, with the anterior end the longer, and rounderl, and the posterior end tapered and angulated, with a slight plication. Hinge-plate well developed, with a delicate, lateral tooth on both sides of the beak in the right valve, and one posterior lateral tooth in the left valve; in both values with the proximal end of the hinge-plate enlarged and thickened near the beak, that of the left valve most dereloped and rising into a blunt tooth-like prominence. Ligament commencing under the beak and ruming back on the ventral side of the posterior hinge-plate, so that for the greater part of its length it is internal.

This genus differs from Cryptodon in the more internal position of the ligament and in having distinet lateral teeth. From Axinodon, in the stronger linge plate, in the presence of the lateral teeth, in laving a posterior plication, and in lacking distinct cardinal teeth.

## LEPTAXINUS MINUTUS, new species.

(Plate LXXXIX, figs. 3-5.)
Shell minute, broadly orate, with a slightly produced obtuse point near the middle of the posterior end, and a somewhat prodnced, broadly rounded anterior end. Beaks behind the middle, rising a little above the dorsal margin and turned forward, leaving a small, rather deep lunular area. Antero dorsal margin a little conver, sloping but little; anterior margin broadly and evenly rounded, forming nearly a semicircle, and passing continuonsly into the ventral margin, which is a little more broadly rounded; the posterior margin is somewhat angular, with a distinct prominence a little below the middle, where the radial ridge terminates, below this for a short spare the mar. gin is neady straight or slightly incurved; above, the posterodorsal margin is straight as far as a slight angle in the ligamental area, above which it is convex to the beak. The hinge-margin is a little thickened, and in the left valve forms a rather prominent and somewhat angular tooth just below and slightly in front of the beak; the ligamental groove is barely visible on the immer face of the posterior hinge-margin, and runs forward as a narrow groove beneath the beak: in the reght valve there is a somewhat less prominent tooth just under the beak, behind which the ligamental groove forms a distinct notch in the margin. Under the microscope there is seen in both valves a distinct submarginal ridge with a conspicnons groove behind it, commencing a considerable distance behind the beak and running in and along the inner hinge-margin; there in also in the right valve a short, indistinct groove along the end of the hinge-margin in front of the beak. Externally a rather shallow, depressed modulation rms from the beak to the pos-tero-ventral margin; behind it is a narrow, but slightly prominent, radial ridge ruming to the posterior angle; back of or above this a rather short ligamental area projects beyond the margin. The surface is covered with a thin, greenish yellow epidermis and is marked by fine, pretty regular, parallel, raised lines of growth, and also faint and rather numerous radiating lines which are not visible except under a high power.

Length, nearly 2 mm .; height, $1 \frac{3}{3} \mathrm{~mm}$.
One live specimen (No. 4568(i), station 949, N. lat. $40^{\circ} 3^{\prime}$, W. long. $70^{\circ}$ $31^{\prime}$, in 100 fathoms, 1881.

## Family ASTARTIDE.

## ASTARTE NANA (Jeffreys?) Dall.

Astarte nana Dall, Bull. Mus. Comp. Zoül., NII, p. 261, pl. vif, figs. 6ia, 6b, 1886; Bull. UT. S. Nat. Mus., No. 37, p. 46, pl. vit, figs. 6a, 6b, 1889.

A single valve, which agrees perfectly with Dall's figures, (uoted above, was foumd at station 2307, off Cape LIatteras, North Carolina, in 43 fathoms, 1SS4. Sonth to Sombrero, in 22 to 196 fathoms.-Dall.

## Family CUSPIDARIDE.

In the elassification of this family we lave adopted the gronps proposed by Messrs. W. H. Dall and E. A. Smith as defined by Mr. Dall. ${ }^{1}$

We, however, consider his two subgeneric groups, Cardiomya and Halonympha, as distinct genera.

## CUSPIDARIA UNDATA Verrill.

(Plates LNXII, fig. 1; LバVIII, figs. 3, 4.)
Neara undata Verrill, Trans. Comi. Acarl., VI, pp. 223, 277, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1888, p. 574, 1885.
Not Myonera undata Dall, Bull. Mus. C'omp. Zö̈l., XII, Pp. 302, 304, 1886; 1;ull. U. S. Nat. Mus., No. 37, p. 68, 1889 (in part).

Three live specimens and two valves were found at stations 2098 and 2566, off Chesapeake Bay, in 2,221 and 2,680 fathoms, 1883 and 1855.

Fragments obtained by the Tilake near Havana, Dominica, and St. Vincent, in 450 to 611 fathoms, are erroncously referred by Mr. Dall to this species. Our shell is certainly not a Myonera.

We liave a fragment of a left valve from station 2655 , N. lat. $27022^{\prime}$, W. long. $78^{\circ} 7^{\prime} 30^{\prime \prime}$, in 338 fathoms, found among Foraminifera, which belongs to a strongly undulated species, with a short, angular, subacute rostrum defined below by a rather (leep groove at which the concentric sculpture changes abruptly. The beak is prominent and turns strongly backward. The cartilage-plate is strong, deeply concave, and directed backward; a moderately elevated internal rib rums backward from the umbonal region to the posterior museular sear. The shell is thin and has deep internal grooves corresponding to the external ridges. Judging by the lines of growth, the shell was shortovate, broadly rounded anteriorly, and having posteriorly a short, angular, subacute rostrum; the escutcheon is concave and well-rlefined by a small, sharp ridge. This fragment seems to belong to an undescribed species of Myonera. It can, however, hardly be the same as Mr. Dall's species, as he states that in his "there is no buttress or appearance of an internal rib."

[^3]CUSPIDARIA LAMELLOSA (M. Sars) Dall.

## (Plate LXXIY, fig. 10.)

> Neara lamellosa Verrill, Trans. Conn. Acad., V, p. 561,1882 ; VI, p. 277 , pl. xxx, fig. 3, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883 , p. 574, 1885.
> Cuspidaria lamellosa Dall, Bull. Mus. Comp. Zö̈l., Xhf, p. 294, 1886: Bull. U. S. Nat. Mus., No. 37. p. 66, pl. Nlv, fig. 3, 1889 .

Comparatively few specimens, at twelre stations, between N. lat. $40^{\circ}$ $2^{\prime} 49^{\prime \prime}$, W. long. $68^{\circ} 49^{\prime}$, and N. lat. $377^{\circ} 59^{\prime} 30^{\prime \prime}$, W. long. $73^{\circ} 48^{\prime} 40^{\prime \prime}$, in 319 to 550 fathoms, 1880-1886.

A few specimens ocenrred which differ from the typical form in having but five or six concentric lamellie visible on the antero-ventral portion of each valve and ouly conspicuons mequal lines of growth on the rest of the surface.

## CUSPIDARIA TURGIDA, new species.

(Plates LXXII, fig. 7; LAXVII, fig. 4.)
Shell rather large, thin, delicate, translncent, of a pinkish white color within, long-oval, with prominent, posteriorly direeted umbos, and narrow, rather long posterior rostrum. The beaks are central, rather acnte and turned distinctly forward. The antero-dorsal margin is slightly convex, forming a broad curve; the anterior end is a little prolonged in the middle but otherwise pretty evenly rounded; the ventral margin forms a regular. broad curve becoming strongly incurved at the base of the rostrum; the posterodorsal margin is straight at first, but slightly concave along the rostrum. The cartilage-plate is small aud very oblique, and in the right valve, is separated by a distinct notch from the lateral tooth, which is long and low, with a rounded summit and a long, gradual, posterior slope; there is no trace of buttress or clavicle. In the left valve the hinge-margin is thin, and nearly simple both anteriorly and posteriorly. The exterior surface is covered with a thin, yellowish gray epidermis and is marked with irregular, rather conspicuous lines of growth; on the rostrum there is a distinct diagonal ridge running from the beaks to the lower margin.

Length, 22 mm .; height, 12 mm .; breadth, 11 mm .; distance from center of beak to end of rostrum, 12 mm . ; to extreme anterior end, 12 mm .

In form, general appearance, and length of rostrum, this species is intermediate between $C$. glaciulis and C. rostruta, but the umbos are more oblique and there are obvious differences in the hinge.

One live specimen (No. 78789), station 2714, N. lat. $38^{\circ} 22^{\prime}$, W'. long. $70^{\circ} 17^{\prime} 30^{\prime \prime}$, in 1,825 fathoms, 1886.

## CUSPIDARIA ROSTRATA (Spengler) Dall.

(Plate LXXII, fig. 6.)
Neer'a rostrata Verrill, 'Trans. Conn. Acad., V, p. 562 , pl. lviil, fig. 39, 1882; VI, p. 277, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 574, 1885.—Snith, E. A., Report Voy. Challenger, Zö̈l. Lamellibranchiata, XII, p. 35, 1885.
Cuspidaria rostrata Dall, Bull. Mns. Comp. Zoü1., XII, p. 294, 1886; XVIII, p. 444, 1889 ; Bull. U. S. Nat. Mus., No. 37, p. 66, 1889.-Locard, Campagne du Caudan, Annales de l'Université de Lyon, p. 177, 1896.
This species was obtained at about fifteen stations between N. lat. $40^{\circ} 6^{\prime} 50^{\prime \prime}$, W. long. $70^{\circ} 3 t^{\prime} 15^{\prime \prime}$, and N. lat. $35^{\circ} 31^{\prime}$, W. long. $73 \circ 21^{\prime}$, in 65 to 156 fathoms. South to Barbados in 65 to 1,639 fathoms.-Dall.

CUSPIDARIA GLACIALIS (G. O. Sars) Dall.

(Plates LXXI, fig. 9; LXXIII, fig. 5; LXXY, fig. 9.)
Neara glacialis G. O. Sars, Mollusca Reg. Arctice Norvegix, p. 88, 11. 6, figs. 8, $a-c$, 1878.-Verrill, Trans. Comin. Acad., V, p. 562, pl. xliv, figs. 10, a-b, 1882; VI, p. 277, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 574, 1885. -Smitir, E. A., Report Voy. Challenger, Zö̈l. Lamellihranchiata, XIII, p. 35, 1885.
Cuspitaria glacialis Dall, Bull. Mus. Comp. Z̀oöl., XII, pp. 291, 303, 1886; Bull. U. S. Nat. Mı , No. 37, p. 66, 1889.

Cuspidaria arctica var. glacialis Dall, Bull. Mus. Comp. Zö̈l., XVIII, p. 44, 1889 ; Proc. U. S. Nat. Mus., XII, p. 280, 1889.
Cuspidaria glacialis Busir, Bull. Mus. Comp. Zö̈l., XXIII, p. 226, 1893.
Not Cuspidaria artica. (M. Sans).
This very common species was dredged at many stations from N. lat. $44^{\circ} 26^{\prime}$, W. long. $62 \circ 10^{\prime}$, to N. lat. $37^{\circ} 8^{\prime}$, W. long. $74^{\circ} 33^{\prime}$, in 62 to 828 fathoms. South to the Gulf of Mexieo, in $6 \pm$ to 1,467 fathoms.-Dall.

## CUSPIDARIA MEDIA, new species.

(Plates LAXI, figs. 万, 6; LXXIII, tig. 6.)
Shell of moderate size, resembling a medinm sized C. glacialis (Sars), in form, but decidedly more swollen, with the rostrum narrower and more distinctly defined by a stronger ventral emargination. Úmbos large, prominent, and swollen, with strongly incurved and very prominent beaks. The antero-dorsal margin is a little convex and slopes rapidly to the evenly romuled anterior end; the ventral margin is regnlarly emved and is rather more convex than in C. glacialis, and shows a very decided emargination at the base of the rostrum; the posterodorsal margin is nearly straight but slopes from the beak to the end of the rostrm which is of moderate length and tapers from the base to the narrow, subtruncated end; it has no distinct diagonal ridge, but is separated from the body of the shell by a strongly marked depression. The surface is nearly smooth but is covered with tine lines of growth
which are most distinct on the rostrum. The hinge-margin is thiu. The right valve has a thin, low, much elongated posterior lateral tooth which runs nearly parallel with the dorsal margin, above which it projects in a broad curve; the cartilage-plate is small, very oblique, and closely united with the tooth from which it is separated by a faint, curved noteh; no buttress. In the left valve there is no lateral tooth, and the cartilage-plate is very small, slightly prominent, with a curved inner edge. The iuner surface of the shell is smooth and the muscular scars are faint.

Leugth of an average specimen, 13 mm . ; height, 8 mm ; breadth, 6.5 mm.; beak to end of rostrum, 8.5 mm . ; beak to auterior end, 6 mm .

This species is allied to C. glacialis, from which it differs in its more swollen form, more oblique anterior end, more prominent ventral margin, more clearly defined rostrum, and straighter postero-dorsal margin. The hinge shows still more decided differences; the lateral tooth of the latter is stouter, more prominent, and less prolonged; the cartilageplate is smaller and less distinctly defined. From C. fraterna it differs in being less produced ventrally and in having a longer rostrum with much straighter dorsal margin and a much longer lateral tooth.

This is a common species off Marthas Vineyard and has been taken at about fifteen stations between N. lat. $40^{\circ} 10^{\prime} 15^{\prime \prime}$, W. long. $500^{\circ} 26^{\prime}$, and N. lat. $39^{\circ} 56^{\prime}$, W. loug. $70^{\circ} 54^{\prime} 18^{\prime \prime}$, in 63 to 155 fathoms, $1880-1884$. A broken valve, station 362, N. lat. $42^{\circ} 1^{\prime}$, $\mathbb{T}$. long. $69^{\circ} 34^{\prime}$, in 106 fathoms, 1879 , is also referred to this species.

## CUSPIDARIA PARVA, new species.

(Plates LAXIV, fig. 9; LXXVII, fig. 7.)
Shell small, delicate, clongated, inequivalved, having a general resemblance in form to the very young of $C$. obesu and $C$. fraterna. Umbos small, rather prominent; beaks small and incurved. 'The antero-dorsal margin is moderately convex and slopes regularly to the evenly rounded anterior end; ventral margin very broadly rounded, with a decided incurvature at the base of the rostrum, corresponding to the marked depression of the surface; postero-dorsal margin slopes rapidly at first and is usually concave along the rostrum, which is moderately long (the length varies in different specimens), narrow, with an obtusely rounded or subtruneated end. It is crossed by a distinct diagonal ridge, above which there are several small, raised, radial lines; the surface is elsewhere nearly smooth or presents a microscopic, faintly granulose appearance. The left valve is the larger and considerably overlaps the right along the ventral margin and siphonal region; the right overlaps the left along the postero-dorsal margin; the rostrum is a little bent toward the left in some specimens. The hinge-margin is delicate, with the anterior margin a little everted; cartilage-plate minute, sunken, in the right valve well separated from the prominent, Proc. N. M. vol. xx- 51
rather elongated lateral tootl; the left valve also has a small, elongated, tooth-like expansion posterior to the cartilage-plate.

Length, 4.5 mm .; height, 2.25 mm .; breadtl, 1.5 mm .
This species may easily be mistaken for the young of $C$. obesa and $C$. fraterma; the structure of the hinge is, however, characteristic.

A comparatively few specimens, at seven station, between N. lat. $41^{\circ} 28^{\prime} 30^{\prime \prime}$, W. long. $65^{\circ} 35^{\prime} 30^{\prime \prime}$, and $35^{\circ} 49^{\prime} 30^{\prime \prime}$, W. long. $74^{\circ} 34^{\prime} 45^{\prime \prime}$, in 515 to 1,290 fathoms, 1883-1886.

## CUSPIDARIA VENTRICOSA, new species.

(Plates LXXII, fig. 5; LAXVI, fig. 6.)
Shell large, rather solid, swollen, with a ventral enlargement and a moderately elongated, tapered rostrum. Umbos swollen and prominent; beaks incurved. Antero-dorsal margin at first nearly straight, then broadly ronded with the extreme anterior end a little prominent; ventral margin decidedly excurved in the middle, corresponding to the exterior swelling; at the base of the rostrum slightly concave; posterodorsal margin somewhat concare, the most so at the base of the rostrum, which is obtusely rounded at the end. Exterior covered with very distinct lines of growth and irregular, stronger, concentric grooves. C : the rostrum there is an obtuse, diagonal ridge running to the ventrus angle of the tip; between this and the dorsal margin there are two others less distinct. The anterior hinge-margin is decidedly thickeued in both valves and projects inward with a thick, ronnded edge, most conspicuous in the right valve, in which it is abruptly much narrowed near the cartilage-plate; in this valve the lateral tooth is short, stout, obtuse, very prominent, and sitnated close to the beak, its length along the margin not much exceeding its height; cartilage-plate small, relatively wide, oblique, directed backward and downward, and closely united to the lateral tooth, there being only a slight, rounded notch between.

Length of the larger specimen, 30 mm .; height, 29 mm .; breadth, 18 mm .; beak to end of rostrmm, 16 mm . beak to anterior end, 17 mm . Another specimen is 25 mm . long; 17 mm . high; 12 mm . hroad.

Four valves, at three station, betweeu N. lat. $40^{\circ} 29^{\prime}$, W. long. $66^{\circ} 4^{\prime}$, and N. lat. $38^{\circ} 27^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ} 54^{\prime} 30^{\prime \prime}$, in 349 to 1,769 fathoms, 1882-1886.

This species has some resemblance to C. glucialis, but is a stouter and more swollen shell, with a relatively larger rostrum, much more elongated and less prominent lateral tooth, and very different cartilageplate. The latter does not have the swollen ventral region, characteristic of our species, nor the diagonal ribs on the rostrum.

# CUSPIDARIA ARCTICA (M. Sars) Dall. 

(Plates LNXI, fig. 2; LNXIT, fig. 7.)

A single imperfect valve from station 70 , south of Halifax, Nova Scotia, in 190 fathoms. is referred to this species. Though worn and slightly broken, it agrees closely with Sars' figure, but it cannot be fully grown, for it measures but 14 mm . in length and 11 mm . in height.

## CUSPIDARIA FORMOSA, new species.

(Plates LXXIT, fig. 6; LNXIX, fig. 3.)
Shell slort, high, and swollen. U'mbos prominent; beaks incurved. Anterior portion broadly romded, a little produced at the end, with the dorsal margin convex and a little excurved; the ventral margin is broadly and evenly rounded; the rostrum is short, broad at base, much tapered; the postero-dorsal margin is nearly straight at first, theu slightly concave and a little upturned. The exterior is covered with meven lines of growth between which the surface is mieroscopieally striated and more or less irịdescent. The color of the single speeimen is pale pink, externally and internally. The right valve has a prominent, triangular lateral tooth with its base prolonged parallel to the margin of the shell; it is separated by a decided notch from the cartilageplate, which is of moderate size, ovate, somewhat oblique, with its inner edge rounded and prominent.

Length, about 16 mm .; height, 13 mm .; breadth, 10 mm .; beak to end of rostrum, abont 9 mm .; beak to anterior end, 8 mm .

A single, much broken, specimen (No. 78313), station 2706, N. lat. $11^{\circ}$ $28^{\prime}$, W. long. $65^{\circ} 35^{\prime}$, in 1,188 fathoms, 1886.

CUSPIDARIA FRATERNA, new species.
(Plates LXXI, figs. 7, 8; LXXY, fig. 6.)
Shell similar to Cospidario obesu (Lovénj, moderately large, considerably swollen, rather thick and firm for the genns, with a moderately long, tapered rostrum. The umbos are rather prominent and swollen, with the strongly incurverl beaks nearly in contact. The anterior end is broadly rounded with a regularly curved. consex dorsal edge which rises nearly to the height of the umbos; the ventral margin is a little protuberant. The postero-dorsal line slopes with a slightly concave outline to the end of the rostrum; on the ventral margin there is a distinctincurvature corresponding to a wave-like depression on the surface,
defining the base of the rostrm. The surface is nearly smooth and somewhat glossy, covered with fine lines of growth which become more prominent and irregular on the rostrum, which has no distinct diagonal line. The hinge-margin is somewhat thickened; the right valve has a rather short, prominent, obtuse, triangular lateral tooth only slightly separated from the cartilage-plate by a concave margin; the cartilageplate is small, very oblique, with the imer edge curved and not at all angulated. Mnscular sears and pallial line indistinct; no buttress.

Length, 13 mm . height, 9 mm . breadth, 6 mm .; from beak to end of rostrum, 8 mm ; from beak to auterior end, 7 mm .

Found at about thirty stations between N. lat. $400 \imath^{\prime} 49^{\prime \prime}$, W. long. $68^{\circ} 49^{\prime}$, and N. lat. $37^{\circ} 23^{\prime}$, W'. long. $73^{\circ} 53^{\prime}$, in 302 to 984 fathoms.

This species resembles C. obesa (Lovén) in form; it is, however, a larger species with a firmer and more swollen shell; the ventral margin is more prominent, so that it has a relatively higher form and is broader at the base of the rostrum. The hinge shows more decided differences, for in ('. obesa the lateral tooth is smaller, shorter, and closely approximated to the cartilage-plate which is distinctly angulated, the inner end being acnte and separated from the tooth by a small angular notch.

CUSPIDARIA OBESA (Lovén) Dall.

## (Plate LXXV, fig. 7.)

Neara obesa Lovén, Ind. Moll. Scand. Occid., p. 48, 1846.-Verrill, Trans. Conn. Acad., V, p. 563, pl. Xliv, fig. 10c, 1882 ; VI, p. 277, 1881 (in part); Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, 1. 574, 1885 (in part).-Smiti, E. A., Report Voy. Challenger, Zoöl. Lamellibranchiata, XIII, p. $43,1885$.

Cuspiduria obesa Dall, Bull. Mus. Comp. Zoöl., XII, p. 295 (not pl. un, fig. 1), 1886 ; Bull. U. S. Nat. Mus., No. 37, 1). 66 (not pl. II, fig. 1), 1889.
Not Neera pellucida Stimpson.
This species has been found at about twenty-four stations between N . lat. $43^{\circ} 23^{\prime}$, W. long. $68^{\circ} 30^{\prime}$, and N. lat. $35^{\circ} 12^{\prime} 10^{\prime \prime}$, W. long. $74^{\circ} 57^{\prime} 15^{\prime \prime}$, in 96 to 811 fathoms, 1873-1887.

It is recorded by Mr. Dall from off Barbados in 100 fathoms and off the coast of California in 16 fathoms.

After a careful study and comparison of the numerous species belonging to the family Cuspidaride we have been able to satisfactorily prove that the form described by Stimpson as Necera pellucidu is quite distinct from that described by Lovén as $N$. obesa, with which it has been so long conformded.

# CUSPIDARIA PELLUCIDA (Stimpson). 

## (Plates LXXV, fig. 8; LXXVI, fig. 8.)

> Seara pellucida Stinipson, Invert. Grand Manan, p. 21. pl. 1, fig. 13, 1853.Goulis, livert. Massachusetts ( 24 ed.), p. 61, fig. 378, 1870.--Verielli, Check-list, p. 24, 1879 .
> Neara sp. Verrill, Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 574, 1885.

Not Neura obesa Lovén.
Shell small, much swollen, with a strongly tapered, somewhat produced rostrum. Umbos relatively large and prominent, beaks minute, strongly incurved. The anterior portion is broadly and evenly rounded, the margin forming nearly a semicircle, with the dorsal margin strongly convex and excurved, rising nearly as high as the umbos; the ventral margin is broadly rounded but distinctly incurved at the base of the rostrum which is rather narrow distally, obtusely rounded at the tip and slightly upturned; the postero dorsal margin slopes considerably, is nearly straight at first but becomes slightly coneave on the rostrum. External surface nearly smooth but usually showing more or less prominent lines of growth, most distinct on the distal part of the rostrum which is destitute of a distinct diagonal line. The right valve has a short, very prominent, strongly enrved lateral tooth rising close to the beak, the most prominent part being near the proximal end which rises rather abruptly from the very minnte cartilage plate from which it is not separated by a notch; just in front of the beak, the hinge-margin is distinctly thickened, sinuons, and a little prominent, forming a sort of tooth, separated from the lateral tooth only by the minute sunken cartilage-plate; the left valve also has a slight, sinnous thickening of the margin in front of the cartilage plate.

Length of one of the largest specimens, 4.5 mm .; beight, 3 mm ; breadth, 3 mm .; beak to end of rostrum, 3 mm .; beak to anterior end, 2.5 mm .

This species has been taken at Eastport Harbor; Bay of Fundy, near Grand Manan Island; and at about twenty-one stations between N. lat. $47 \circ 40^{\prime}$, W. long. $47^{\circ} 3 \overline{5}^{\prime} 30^{\prime \prime}$, and N. lat. $35^{\circ} 14^{\prime} 20^{\prime \prime}$, W. long. $74^{\circ} 59^{\prime} 10^{\prime \prime}$, in 52 to 516 fathoms, 1868-1886.
The specimens here described are from the Bay of Fundy, near Grand Manan Island and Eastport Harbor, very near the locality where Doctor Stimpson's types were obtained. In former articles we have united this species with C. obesa (Lovén). A careful reexamination of a large series of specimens of both forms has convinced us that they are distinct but elosely related species. In C. obeset the anterior portion is more produced, giving the shell a more ovate outline; the rostrum is broader and rather more upturned; the cartilageplate is relatively much larger, more prominent, and angular at the edge, and in the right valve is separated from the lateral tooth by an
angular notch; while the tooth itself is relatively smaller, shorter, less prominent, and more distinctly triangular in form.

## CUSPIDARIA SUBTORTA (Sars).

> (Plates LXXIII, fig. 1; LXNIV, figs. 4, b.)

Neara subtorta sars, G. O., Mollusca Reg. Aretice Norvegix, p. 87, pl. 6, figs. 6, a-c, 1878. -Jeffreys, Anin. Mag. Nat. Hist., p. 234, September, 1877; l'roc. Zoïl. Soc., Londou, p. 937, November, 1881.-Snith, E. A., Report Voy. Challenyer, Zö̈l. Lamellihranchiata, XIII, p. 35, 1885.
Shell inequivalve, rather short, relatively high, much swollen in the middle, with tumid umbos and a short, tapered, somewhat upturned rostrum. The anterior portion is broadly rounded, the margin forming nearly a semicircle; the antero-dorsal margin is strongly convex and slightly excurved; the ventral margin is evenly romded, except at the base of the rostrmm where it is distinctly incurved, especially in the right valve; the postero-dorsal margin is very strongly concave in the left valve and less so in the right. The rostrum is separated from the body of the shell by a simous depression and has a poorly defined diagonal ridge; it is a little bent to the left and. when viewed from above, appears slightly twisted. The surface of the shell is nearly smooth, but shows distinct lines of growth anteriorly, and especially on the superior part of the rostrmm; the epidermis is very thin, yellowish white, more or less wrinkled on the rostrum; the hinge-margin is rather strong; the lateral tooth in the right valve is large, rather elongated, rather prominent, obtusely triangular, and not separated from the very small, narrow, oblique, sunken cartilage-plate by a noteh; in the left valve there is a small, short, prominent tooth arising from the posterior margin of the cartilage-plate and separated from the posterior hinge-margin by a distinct angular noteh.

Length, $S \mathrm{~mm}$.; lıeight, 6 mm . ; breadth, abont 5 mm .
One live specimen (No. 52545 ), station 2499 , N. lat. $44^{\circ} 46^{\prime} 30^{\prime \prime}$, W. long. $59^{\circ} 55^{\prime} 45^{\prime \prime}$, in 130 fathoms, 1885.

This species appears to be identical with the European subtorta. It differs from all of our other speries in having a distinct tooth-like tuberele belind the cartilage-plate in the left valve. The inequality of the valves and the twisted rostrum give the shell a peculiar aspect.

## CARDIOMYA ABYSSICOLA, new species.

## (Plates LXXIII, fig. 4; LXXIY, fig. 1; LXXVII, fig. 9.)

Shell rather large, swollen, with tumid umbos; outline elongate-ovate, with a narrow, rather elongated, tapered, slighty excurved posterior rostrum, the tips divergent and gaping; the anterior end is broadly round, with the dorsal and rentral margins convex, the latter namowing gradually posteriorly with a slight sinus at the base of the rostrum; the postero-dorsal margin is concave, so that the end of the rostrum is
somewhat upturned. The eutire body of the shell is covered with numerons narrow, elevated, radiating ribs, separated by much wider concave interspaces, some of the widest of which have a small secondary rib in the ecnter toward the margin; the ribs increase in elevation and strength posteriorly, toward the base of the rostrum, but never become broad; for a short distance on the base of the rostrum the ribs are nearly obsolete but become prominent again on its dorsal and terminal portions; this part is also crossed by irregular raised lines of growth which cross the ribs obliguely; the imer surface is covered with rounded grooves corresponding to the external ribs, separated by convex ribs of about the same width; these become obsolete anteriorly and posteriorly. The linge-margin in the left valve is only a little thickened and slightly exeurved, the cartilage-plate is central, stont, regularly ovate in form, with a thickened imer margin; in the right valve there is a prominent, rather stout, elongated posterior tooth, the anterior end of which joins closely the cartilage-plate, leaving searcely any notch between; the highest part of the tooth is near the middle, the slope, however, is a little steeper anteriorly; a deep groove separates the tooth from the thin, slightly excurved dorsal margin; anteriorly the margin is but slightly thickened, and shows a very narrow, beveled edge externally for the attachment of the thin ligament; a similar but more distinct ligamental groove extends from the beak to the base of the rostrum; there is a short, rather stont, rib-like clavicle or buttress rmming from beneath the middle of the tooth obliquely backward and downward in the direction of the base of the rostrum; a less prominent buttress is also present in the left valve.

Length of one of the largest specimens, 25 mm .; height, 15 mm ; thickness, 14 mm .; from beak to end of rostrum, 13 mm .; to anteroventral margiu, 12 mm . One badly broken valve is considerably larger than this. There are also two young live specimens which measure about 6 mm . in length and 3.5 mm . in height. Their form is somewhat narrower and longer than in the adult, and the rostrum appears rather longer and narrower; the posterodorsal margin is nearly straight; the ventral margin is decidedly concave at the base of the rostrum; the shells are very thin, somewhat transparent and glossy, and have about twenty-six sharply defined, considerably elevated, nearly equal, narrow ribs on the body of the shell, separated by moch wider spaces; the elge of the left valve overlaps that of the right, especially along the hase of the rostrum.

In general appearance this species greatly resembles C. multicostata Verrill and Smith. It differs, however, in having a regularly more ovate form with the anterior region somewhat narrower and more prolonged and the postero-ventral margin less ineurved at the base of the rostrum, so that the latter is broader and less differentiated. The external coste differ in being narrow and sharp, separated by broad coneave interspaces, and of nearly uniform size, there being no marked contrast between those ou the anterior and posterior portions of the shell,
although the elevation and distance between them gradually increase posteriorly, while in the former they are broadly rounded and separated for the most part by narrow interstices. The hinge also differs considerably; the cartilage-plate is less prominent and broader than that of multicostuta, and the tooth in the right valve is longer and not so prominent and scarcely forms a notch at its junction with the cartilageplate; anteriorly the margin is very thin and simple with a very narrow, linear, ligamental groove along its onter edge, while in the former the groove is broader and its inner edge is raised almost in the form of a lateral tooth.

It also resembles $O$. costellata var. corpulenta Dall in the character of the costee, but the latter is much shorter and higher in form and has a very short, ill-defined rostrum.

Two young live specimens, two separate valves, and some fragments were taken at three stations, between N. lat. $40^{\circ} 29^{\prime}$, W. long. $66^{\circ} 14^{\prime}$, and N. lat. $36^{\circ} 47^{\prime}$, W. long. $73^{\circ} 9^{\prime} 30^{\prime \prime}$, in 1,685 to 1,813 fathoms, 1885-86.

## CARDIOMYA MULTICOSTATA Verrill and Smith.

## (Plate LXXIII, fig. 3.)

Negra multicostata Yerrill, Trans. Conn. Acad., V, p. 559, pl. lvini, fig. 40, 1882; VI, p. 277, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, pl. xxx, fig. 129, 1885.-Suiti, E. A., Report Voy. Challenger, Zoül. Lamellibranchiata, XIII, p. 36, 1885.

Neara multicostata var. curta Verrill, Trans. Conn. Acall., V, p. $560,1882$.
This comparatively rare species was found at but eight stations off Marthas Vineyard, in 85 to 158 fathoms, 1880-1883.

Although this species resembles Cardiomya striata (Jeffreys) in the character of its sculpture, the marked difference in outline, especially in its clearly defined rostrum, reuder it advisable to keep the two forms separate until a careful comparison of the hinges can satisfactorily decide the question of their identity.

The two valves designated as varicty curta have the radiating ribs rounded and not angular, but fewer in number than the typical form, and must be distinct from curta of Jeffreys, which Mr. Dall makes a variety of costellatu of Deshayes.
(Plates LふXIII, fig. 2 ; LNXIV, fig. 3.)
Neara perrostrata Verrill, Trans. Conn. Acad., V, p. 561,$1882 ;$ VI, p. $277,1884$.

Only a few specimens were obtained from seven stations between N . lat. $40^{\circ} 15^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ} 25^{\prime}$, and N. lat. $39^{\circ} 46^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ}$ $54^{\prime}$, in 58 to 3.5 fathoms, $1850-1884$.

South to Granada, in 339 to 416 fathoms.-Dall.

## CARDIOMYA GEMMA, new species.

(Plates LXXI, figs. 3, 4; LXXIV, fig. 11.)
Neara paucistriafa Bush, Trans. Conn. Acad., VI, p. 473, 1885.
Not Myonera paucistriata Dall, Bull. Mus. Comp. Zö̈l., XII, p. 302, 1886; Bull.
U.S. Nat. Mus., No. 37, p. 68, 1889 ; Proc. U.S. Nat. Mus., XII, p. 233, pl. xif, fig. 12, 1889.
Cardiomya sp. Bush, Bull. Mus. Comp. Zö̈l., XXIII, p. 227, 1893.
Shell small, inequivalyed, thin, fragile, translucent, bluish white, somewhat ovate, with a well-defined rostrum. Umbos smooth, a little prominent; the beaks small, inconspicuous. The antero-dorsal margin is convex and rises distinctly abore the beaks so that the greatest height of the shell is in front of them; thence it slopes rapilly to the somewhat prominent anterior end; the ventral nargin is broadly rounded with a slight angle at the termination of each radial rib, decidedly incurved at the base of the rostrum which is a little elongated, nearly straight, somewhat tapered, and rather upturned distally; the posterodorsal margin is depressed and somewhat concave. Each valve has three conspicnous, prominent, thin, elevated, distant, radial ribs on the posterior half and a fourth less distinct one at abont the middle; this is rudimentary in the left valve; none of them reach the umbos. The surface is also covered with very delicate lines of growth; the rostrum does not have a diagonal ridge. The hinge-margin is thin and delicate; the right valve has a small but prominent, moderately long lateral tooth separated from the rery minnte cartilage-plate by a distinet notch. The lateral tooth is supported by a small buttress.

Leugth, 5 mm . ; height, 3 mm .
A few specimens off Cape Hatteras, North Carolina, in 16 and 17 fathoms, 1884.

## CARDIOMYA GLYPTA Bush.

(Plates LXXI, fig. 1; LXXVI, figs. 3, 7.)
Neara costata Bush, Trans. Conn. Acad., VI, p. 472, pl. xhry, fig. 21, 1885; Expl. Allatross, Report U. S. Com. Fish and Fisheries for 1883, p. 587, 1885; not Sowerby, 1834.
Cardiomya ormutissima Dall, Bull. Mus. C'omp. Zoül., NIl, p. 296, 1886; Bull. T. S. Nat. Mus., No. 37, p. 66, pl. xli, fig. 21, 1889.

A few specimens were found at two stations off Cape Hatteras, North Carolina, in 48 fathoms. South to Guadaloupe, in 2 to 124 fathoms.Dall.

In addition to the published description it should be stated that the antero dorsal margin of the right valve rises into a distinct, prominent, obtuse lobe in front of the tooth; this lobe overlaps the margin of the left valve when the shell is closed. There is a small buttress beneath the posterior lateral tooth. Oue broken valve, considerably larger than the type, has in the intervals between the three primary ribs two or three small secondary ones; on the anterior end six ribs are visible, of which one or two are larger than the rest, so that altogether abont thirteen or fomteen ribs can be connted; some of these are, however, very small and extend only part way to the umbo; even the largest do not extend over the extreme part of the umbo.

Mr. Dall considers this species to be identical with D'Orbigny's ornatissima, but we see no sufficient reason for miting the two forms.

The name costata was used by Sowerby in 1834.

HALONYMPHA STRIATELLA, new species.
(Plates LXXII, figs. 2, 3; LXXVII, fig. 10.)
Shell small, thin, broadly and obliquely ovate, with a narrow, short rostrum. Umboswollen. Beak behind the middle. The antero-dorsal margin is broadly and nearly evenly convex; the anterior end is evenly rounded; the ventral margin is broadly convex with a slight incurvature at the base of the rostrum, which is short, narrow, and obtuse at the end; the postero-dorsal margin is strongly coucave and slopes rapidly. In the region of the umbo the surface is lustrons and nearly smooth, but marked with faint, parallel lines; elsewhere it is closely covered with very regular, fine, raised concentric lines separated by incised lines of about the same width or narrower; on the rostrum there is a faint diagonal ridge posterior to which the concentric lines are irregular. The interior surface is smooth and lustrous but the external lines show throngh by transpareney. In the right valve there is a small, sharp, triangılar tooth projecting inward with a very small eartilage-pit in front of and confluent with it; slightly farther forward there is another small, slender tooth rising nearly parallel with the
margin; external to this there are remnants of a small anterior ligament occupying a short furrow. Commencing behind the beak and extending to the base of the rostrum, there is a comparatively large and prominent lamelliform process rising from beneath the margin and projecting downward, with the face portion broadly rounded, and its upper surface concave. Above the base of this, and extending from near the beak to about the middle of the rostrum, is a narrow, slightly thickened ridge separated from the dorsal margin by a narrow furrow.

Length, 6 mm .; height, $4.5 \mathrm{~mm} . ;$ breadth, about 3 mm .
One valve, station 2655, among Foraminifera, N. lat. $27^{\circ}$ 22', W. long. $78 \circ 7^{\prime} 30^{\prime \prime}$, in 338 fathoms, 1886.

This species has considerable resemblance to H. clariculata I all, but the latter is more regularly ovate in form, and has a much shorter aud broader rostrom, and somewhat coarser sculpture. The posterior shelf-like clavicle also differs in form, being ruite narrow for a considerable distance next the cartilage-pit, and more expanded distally. The shell described and figured by Smith ${ }^{1}$ under the same name appears to be a distinct species, and may be identical with our shell, for it has nearly the same form and agrees closely in the narrow tapered rostrmm. The figure of the interior, however, in that case, is incorrect, owing to the omission of the clavicle, and apparently the substitution of the hinge of the left valve for the right.

## MYONERA GIGANTEA Verrill.

## (Plate LXXVI, figs. 4, 5.)

Neara gigantea Terrill, Trans. Conn. Acad., VI, pp. 223, 277, 1884; Expl. Albatross, Report U.S. Com. Fish and Fisheries for 1883, 1. ist, 1885.

Three imperfect, dead specimens have been found at three stations between N. lat. $38^{\circ} 22^{\prime}$, W. long. $70^{\prime} 17^{\prime} 30^{\prime \prime}$, and N. lat. $37^{\circ} 56^{\prime} 20^{\prime \prime}$, W. long. $70^{\circ} 57^{\prime} 30^{\prime \prime}$, in 1,825 to 1,917 fathoms, 1883 and 1886.

MYONERA RUGINOSA (Jeffreys) Verrill and Bush.
(Plates LXXII, fig. 4; LXXIV, fig. 2.)
Nepra ruginosa Jeffreys, Proc. Zö̈l. Soc. London, p. 942, pl. LXXi, fig. 7, November, 1881.-Smitn, E. A., Report Voy. Challenger, Zö̈l. Lamellibranchiata, NIII, p. 35̃, 1885.

Shell small, short, broad-orate, not much swollen, with a short, wide, gaping, obliquely truncate rostrum. Umbos small, prominent, not much swollen; beaks small, prominent, incurved, smooth and shining. The anterior portion is eveuly rounded, nearly semicircular; the anterodorsal margin is convex and prominent; the ventral margin is broadly and evenly rombled, except at the base of the rostrm where it is sinuous and incurved; the postero-dorsal margin is nearly straight to the

[^4]end of the short rostrum which has a distinct, median, diagonal ridge or angulation and another less distinct one at its base. The surface of the shell is thickly covered with very mmerons, and crowded, concentric, more or less irregular, raised lines of growth which give it a finely lamellose appearance when viewed under a lens. These lines become more crowded, more prominent, and form two sinnous waves in crossing the rostrum. Color, in alcohol, white tinged with reddish brown. The hinge-margin is delicate; the right valve has no lateral tooth but shows a slight thickening of the posterior margin; the cartilage-phate is small, ovate, directed backward.

Length, 6 mm .; height, 4.5 mm .; breadth, 3 mm .
One live specinen (No. 52544), station 2570, N. lat. 390 54', W'. long. $67^{\circ} 5^{\prime} 30^{\prime \prime}$, in 1,813 fathoms, 1855.
"Porcupine Expedition, 1870," off" Cape Mondego, in i40 to 1.095 fathoms.-Jeffreys.

## MYONERA LIMATULA Dall.

## (Plate LXXIV, fig.8.)

Neura limatula Dall, Bull. Mus. Comp. Zö̈l., LX, p. 112, 1881.-Smiti, E. A., Report Voy. Challenger, Zoöl. Lamellibranchiata, XII, p. 35, 1885.
Myonera limatuta Dall, Bull. Mus. Comp. Zoöl., XII, p. 30t, pl. iif, fig. 5, 1886; Bull. U. S. Nat. Mus., No. 37, p. 68, pl. III, fig. 5, 1889.
A single live specimen (No. 38171) was taken at station 2048, N. lat. $40^{\circ} \mathbf{2}^{\prime}$, W. long. $68^{\circ} 50^{\prime} 30^{\prime \prime}$, in 547 fathoms, 1883.

MYONERA (?) PRETIOSA, new species.
(Plate LXXVII. fig. 5.)
Shell small, very thin and fragile, nearly transparent, compressed, elongate-oval with a well-defined, somewhat elongated rostrum. Umbo prominent, searcely oblique and nearly smooth. The antero-dorsal margin is convex, anterior end evenly romded; ventral margin broadly convex, becoming incurved at the base of the rostrum; posterodorsal margin nearly straight. The antero dorsal region is distinctly excavated in front of the beaks. The body of the shell is ornamented with ten or more thin, distinet, slightly raised, concentric riblets separated by much wider interspaces. On the rostrum there are two well-marken minutely spimmlons keels between which are delicate lines of growth; the first runs from the beak quite close to and parallel with the dorsal margin; while the second extends from the umbo diagonally across the rostum to its lower edge.

Length, 6 mm .; height. 3 mm .; breadth, about 2 mm .
This shell has no very close resemblance to any hitherto described.
One valve, station 2655, N. lat. $27^{\circ} 2^{\circ} 2^{\prime}$, W. long. i $807^{\prime} 30^{\prime \prime}$, in 333 fathoms, among Foraminifera, 1886.

As but a left valve was found, the true position of this species can not be decided.

## Family POROMYIDAE.

POROMYA SUBLEVIS Verrill, variety MICRODONTA Dall.

> (Plates LXXYI, figs. 1, 2; LXXXYIT, fig. 1.)
Poromya subleris Verrill, Trans. Conn. Acad., VI, pp. 221, 277 , pl. xxxn, fig.
21, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883,
p. 574 , pl. xxx, fig. 128, 1885.-Dall, Bull. Mus. Comp. Zö̈l., NII, pp. 281,
282, 1886 ; XVIII, p. 448, 1889 (varicty?) ; Bull. U. S. Nat. Mus., No. 37, p.
68 , pl. LXT, fig. $128,1889$.
Poromya microdonta Dall, Proc. U. S. Nat. Mus., XII, p. 290, pl. viri, fig. 6, 1889
(variety?).

Shell rather large, thick, well-rounded, cordate, inequivalved, very tumid, with very large, prominent umbos which are strongly enrved forward spirally; beaks large; lmmle small, cordate, often not very distinct. The shell varies considerably in outline and size and elevation of the umbos; in most specimens the height equals or slightly exceeds the length; the ontline of the cavity of the shell is usually somewhat elliptical, the length decidedly exceeding the height, but sometimes it is nearly circular. The anterior and posterior margins are usually pretty evenly rounded; the ventral margin usually projects a little in the middle; the beak is situated in front of the median line. Esternally the shell is nearly smooth and is covered with a thin, closely adherent, brownish-yellow epidermis; under a lens the surface shows minute raised points or granules which are arranged in radial rows that become more distinct and crowded posteriorly but for the most part disappear on the most prominent part of the umbos. These grannle-like points are variable in mmber and distinctness, in some specimens being nearly obsolete and in others distinet and regularly arranged; the epidermis often also shows fine lines of growth; the beaks are smooth and shining. The left valve has a posterior, wave-like, radial depression, and behind this a low, rounded ridge projecting at the margin as a slight siphonal lobe: in the right valve, the corresponding lobe and depression are only faintly marked in most cases. The right valve is larger than the left and overlaps it considerably aloug the ventral margin and both in front of and behind the beaks. The interior is pearly and often shows radial striations. The hinge-margin is considerably thickened and strongly curved; the right valve has a large, thiek, somewhat rounded tooth just beneath the beak and adnate to the inner surface of the shell, for some distance within the cavity of the beak and to the thickened edge behind the beak, but separated from the anterior margin by a deep, curved furrow in the lunular area; the lumular margin is convex and somewhat everted, separated from the rest of the anterior margin by a slight noteh. The ligament is rather long and well-rounded and its groove extends forward in a curved furrow under the beak; it extends backward in a curved line parallel with the margin of the shell for some distance
behind the tooth. External to the posterior part of the ligament there is a submarginal thickening or fold, especially in the right valve. In the left valve the central tooth is represented by an irregular, bilobed, or somewhat $V$-shaped thiekening of the margin, of which the auterior part, situated just in front of the beak, is the more prominent; but this varies in form in different specimens. The postero-dorsal margin along the ligamental region is less thickened but has a distinct rounded ridge inside the ligament.

Length of one of the largest specimens, 16 mm ; total height, 16 mm ; height of cavity, 12 mm .; breadth, 16 mm . In a more romded specimen the length is 15 mm .; total height, 16 mm .; height of cavity, 13.5 mm . ; breadth, 14 mm .

A few dead specimens of the typical form (sublecis) have been taken at five stations between N. lat. $39^{\circ} 15^{\prime}$, W. long. $68^{\circ} 8^{\prime}$, and N. lat. $37^{\circ} 56^{\prime} 20^{\prime \prime}$, W. long. $70^{\circ} 57^{\prime} 30^{\prime \prime}$, in 1,594 to 1,917 fathoms, $1883-1886$.

Several live and dead specimens of the varietal form (microdonta) have been taken at eight stations between N. lat. $39^{\circ} 26^{\prime}$, W. long. $68^{\circ} 33^{\prime} 30^{\prime \prime}$, and N. lat. $36^{\circ} 47^{\prime}$, W. long. $73^{\circ} 9^{\prime} 30^{\prime \prime}$, in 1,631 to 1,859 fathoms, 1885-1886.

Mr. Dall extends the range south to Patagonia, in 122 to 1,635 fathoms.

Our specimens show considerable variation in form as well as in the prominence of the cardinal tooth in the right valve, and thus unite the extreme forms $P$. sublevis Verrill, and $P$. microdonta Dall.

CETOCONCHA ATYPHA, new species.
Shell short ovate, nearly equilateral, and nearly equally rounded at both ends, judging from the lines of growth. Umbos rather prominent, but less so than in several allied species. Beaks rather prominent and curved strongly forward, but not spiral. Surface somewhat shining and slightly iridescent where rubbed, covered with a very thin, yellowish epidermis with very numerous, minute, granule-like elevations which are arranged in regular radiating lines, and are much the most numerous on the posterior end where the radial rows are closely crowded and the granules in each are also near together; on the center the rows and granules are more distant, so that the number is only about half as great in the same space; on the anterior end they are so scattered that the radial rows are indistinct and the granules are a little larger; on the lunular area they are nearly obsolete. The anterior end and lunular area are marked by rather conspicuous lines of growth which, near the dorsal margin, take the form of distinct, raised, concentric ridges. The anterodorsal margin is nearly horizontal and rises up, in a side view, in an acute edge, a little higher than the level of the beak, so as to produce a broad, compressed, lunnlar margin. When viewed from above, this part of the margin forms a very marked obtuse angle with the posterior hinge-margin. The postero dorsal margin is also nearly
horizontal, slightly convex or nearly straight; the ligament is very prominent behind the beak, extending backward in a conspicuous groove nearly to the posterior end, and terminates auteriorly in a deep narrow groove directly under the beak. In the left valve the inner edge of the posterior linge-margin is somewhat sinuons; just behind the beaks, opposite the most prominent part of the umbos, it is thickened and somewhat revolute, decreasing both in thickness and elevation to a shallow indentation of the margin; back of this, it inereases regularly in thickness and prominence and is again revolute along the posterior part of the ligamental furrow. There is no central tooth nor any distinct resilium. In the right valve the posterior hinge-margin is even more thickened and revolnte just back of the beaks, and the indented, thinner portion, at the end of the prominent part of the ligament, is more marked. The ligamental groove is consequently less conspicuous, being partially concealed by the recolute margin. The antero-dorsal margin is compressed and projects strongly upward, rising distinctly above the umbos in a side view and is more convex than in the left ralve. There is also a slight elevation within the dorsal margin directly below the beaks, which might be considered the rudiments of a tooth.

The largest specimen, when perfect, would be about 15 mm . long.
Two very much broken valves, station 2ner $^{2} 9$, N. lat. $37 \circ 38^{\prime} 40^{\prime \prime}$, W. long. $73^{\circ} 16^{\prime} 30^{\prime \prime}$, in 1,423 fathoms, 1884.

This species somewhat resembles Cetochonca nitita (Verrill) ${ }^{1}$ Dall. ${ }^{2}$ It is however more oblong, with the umbos much smaller and less prominent and the beaks less spiral and nearer together. The granulation of the surface is somewhat stronger and more generally distribnted. The ligamental groove is longer, deeper, and the ligament itself is more prominent behind the beaks. The angulation of the hinge-margin of the left valve in a horizontal plane is a peculiar feature not found in the other related species and indicates that the valves are decidedly unlike in form, but the right ralve is too much broken to show the anterior margin.

## CETOMYA species.

A broken left valve (No. 52013) from station 2481, N. lat. $44^{\circ} 7^{\prime} 30^{\prime \prime}$, W. long. $55^{\circ} 16^{\prime} 45^{\prime \prime}$, in 116 fathoms, resembles Poromya (Cetomya) elonguta Dall, from the West Indies and Barbados, in 100 to 119 fathoms. It is, however, too incomplete for determination without direct comparison with authentic specimens.

It is larger and more strongly truncate posteriorly than Poromya granulute (Nyst) Forbes and Hanley, and the grannles are coarser and not so numerous. It differs, moreover, very strongly in the linge characters, for the hinge-plate is much thinner and the large tooth in the left valve is wanting in our species.

[^5]
## Family VERTICORDIDA.

## VERTICORDIA GRANULIFERA (Verrill) Dall.

(Plates LXXXVII, fig. 2; XCV, figs. 2, 3, 4.)
Pechiolia granulifera Verrill, Traus. Comn. Acad., VI, pp. 434, 448, 450, 1885.
Ferticordia granifera Dall, Bull. Mus. Comp. Zö̈l., NII, p. 286, 1886.
Verticordia graulifera Dall, Bull. U. S. Nat. Mus.. No. 37, 1. 66, 1859.
In addition to the published description, it shonld be stated that in the type-specimen (No. 44838 ), the lumular area is small, deeply sunken, with the corresponding internal margin very much thickened, forming a strong, curved, tooth-like projection having a rounded summit, reaching strongly above the margin of the shell when seen in a profile view; behind this, directly nuler the beak and beneath the overhanging margin, there is a triangular space or notch for the reception of the prominent tooth of the opposite valve; this is followed posteriorly by a short, triangular, shelf-like projection, a little beneath the margin, which has a depression on its upper surface for the reception of its ligament but shows, in this specimen, no motch or scar corresponding to the ossicle. Directly under the strongly incurved beak there is a slight, thin groove in which the front part of the ligament was attached. The postero-dorsal edge is a little thickened and projeets inward beyond the general line of the margin; its outer surface has a smooth, slightly excavated groove, extending parallel with the edge, for some distance; this portion was overlapped by the projecting edge of the opposite valve.

A very large specimen (No. 78679) from station 2713, which measures 21 mm . in length, $22 \frac{1}{2} \mathrm{~mm}$. in height, and 10 mm . in thickness, has, in the right valve, directly beneath the beak, a very strong, high, curved, pointed, angular tooth attached by a very broad, thick base, a considerable distance within the margin. Behind the ossicle, well within and nearly parallel with the margin for its entire length, is a conspicuous shelf-like ridge against which the projecting edge of the opposite valve rests. The ossicle is strong, somewhat rectilinear in ontline, with the posterior end deeply forked, the inner surface strongly convex, the outer strongly concave, with thick, somewhat beveled edges, to which the ligament is attached. Interior surface somewhat pearly. Scars and pallial line not very clearly defined.

But four specimens, beside the type, have been found at four stations between N. lat. $40^{\circ} 9^{\prime} 30^{\prime \prime}$, W. long. $67^{\circ} 9^{\prime}$, amr N. lat. $36^{\circ} 47^{\prime}$, W. long. $73^{\circ} 9^{\prime} 30^{\prime \prime}$, in 1,356 to 1,859 fathoms, $1884-1886$.

## Family LITONSIELLID.E.

## LYONSIELLA SUBQUADRATA (Jeffreys.)

(Plate LXXXIII, fig. 3.)

Pecchiolia subquadrata Ieffreys, P'me. Zoïl. Soc. London. p.932, pl. 1.xx, lig. 3, November, 1881. - Not Dall, Bull. Mus. Comp. Zö̈l., Nil, p. 272, 1N86.

Onr specimen seems to agree in every respect, except size, with the original description and figure as given by Jeffreys, ours being considerably larger.

The momo is prominent and the beak is eurved strongly forward, producing a deep lunular area which is defined neither by a groove nor a ridge. The surface is everywhere covered with small but prominent gramules which are numerons, pretty evenly spaced, and arranged somewhat distinctly in radiating rows which, under the microscope, are defined by slight radial ridges uniting those of the same row. The gramulations are easily visible with slight enlargement. Under the compound microscope they have the form of elevated, acute cones and blunt tubercles, their height usually greater than their diameter, except on the nmbo, where they are low and rounded. Internally the surface is everywhere marked with small, deep pits looking like punctures made by a fine needle, and corresponding to the external granules. The hinge margin is thickened and entirely edentulons, as described by Jeffreys. I'osterior to the beak there is a distinct groove in the thickness of the margin for the reception of a ligament. Beneath the beak there is a slight, oblique, marginal notch or slit for the reception of the resilinm, running back within and underneath the dorsal margin, so that it is scarcely visible in a direct front view.

This shell appears to be identical with the species originally described and figured by Jeffreys under the name of Pecchiolin subquadrata. Mr. Dall has evidently found an entirely different species in the Jeffrey's collection under this mame, which he has referred to the gemus Cullocardia and subgenus Tesicomy, belonging to an entirely different family from our shell. In order to avoid confusion the shell examined and described by Mr. Dall should receive a distinct specific name; we therefore propose Callocardia (Tesicomya) dalli. Mr. Dall states that "the sparsely set, microscopic tubereles can only be observed with a magnifier; to the eye the surface looks shining and smooth," which shows the surface to be quite different from that of our shell. In his shell there are also two cardinal teeth in each valve.

One valve (No. 78800 ), station 2714 , N. lat. $38^{\circ} 22^{\prime}$, W. long. $70 \circ 17^{\prime}$ $30^{\prime \prime}$, in 1,825 fathoms, 1886.

North of the Hebrides, in $54{ }^{2}$ fathoms; and off Cape Mondego in Vigo Bay, in 740 to 1,095 fathoms. "Porcupine Expedition, 1869-70."Jefficys.

Proc. N. M. vol. xx- 52

## LYONSIELLA CORDATA, new species.

> (Plate X(V, figs. 7. 8.)

Shell rather large and firm for the genus, somewhat translucent bhish white, swollen, cordate, with a posterior obtuse prominence. I'mbos prominent, turned forward spitally; beaks small, strongly incurved. Limule smail, cordate, defined only by one of the ordinary fine radial ridges; the part that lies immediately under the beak is deeply sumken with the edge pinched up into a prominent keel. The anterodorsal margin is strongly convex and prominent in the lunular region, but not so high as the mubos; the anterior margin is but slightly convex and nearly perpendicular to the axis of the shell; the ventral margin is strongly convex and somewhat prodnced in the middle, farther bark it is but slightly convex; the posterior end is obtusely rounded, decidedly prominent lut not angular; the postero-dorsal margin is a little convex and slopes gradnally. The surface is covered with about sixty delicate, radiating, raised lines or riblets which are crossed by fine lines of growth, the thin, brownish or grayish green epidermis oftei rising into small points at their intersection, especially anteriorly and posteriorly; these riblets become coarser and more dis tant anteriorly, and are lacking on the lunule. The ligament is thin and strong and extends backward along nearly the whole of the dorsal margin and curves spirally under and around the beak in the region of the resilium, so that the two come almost in contact. The hinge margin, in front of the beak and lonular area, is strongly convex and protuberant, rising nearly to the height of the umbo; posteriorly it is convex and thin in both valves; in the left one it is strengthened by a slight marginal rib within the ligamental furrow; both of these are less evident in the right valve. There are no teeth in either value. The ossicle is relatively large, oblong, somewhat saddle-shaped, narrowest and truncated anteriorly, broadest and forked posteriorly, the divisions alcute. The resilium beneath the ossicle is well developed. dark hrown, and extends forward and upward to the margin, heneath the beak.

Length of the largest specimen, 11 mm .; height, 12 mm . Another is 11 mm . $\mathrm{l} \mathrm{mg} ; 71.5 \mathrm{~mm}$. high; 9 mm . broad.

Two living specimens and one valve, at three stations between N. lat. $39 \supset 15^{\prime}$, W. long. fiso $8^{\prime}$, and N. lat. $37^{\circ} 38^{\prime} 40^{\prime \prime}$, W. long. $73^{\circ} 16^{\prime} 30^{\prime \prime}$, in 1,423 to 1,525 fathoms, $1884-1886$.

## Family LYONSIDA.

> LYONSIA GRANULIFERA, new species.

> (Plate XCV, fig. 1.)

Shell oblong, trmonated posteriorly, narrowed and romed anteriorly. Umbo rather prominent with the beak in front of the middle and curved forward; lunular area considerably sunken. Anterior end evenly
rounded with the dorsal margin rapidly sloped; ventral margin broadly and evenly rounder ; posterion end somewhat obliquely trmeated without any definite boundary, but with a distinct depression extending from under the beak to about the middle of the posterior margin; postero dorsal margin nearly straight, longer, and sloping less rapidly than the anterior. The entire surface is covered with minnte, irregular, raised, gramules and pretty distinct, but irregular, lines of growth and slightly raised, distant, thin, radiating lines ruming from the umbo to the margin, except on the posterior end where the lines of growth become more prominent; these radial lines are however, in many places, rather faint and seem to consist mainly of the thin, brownish epidermis, which is lacking in certain parts. Minute grains of sand and shells of Foraminifera are firmly adherent to the surface, mainly along the radial lines, and especially posteriorly. The interior is white, hustrons and but slightly nacreons. Mnscular and pallial scars indistinct. The hinge-margin is thin; in the left valve the anterior border is somewhat thickened in the lunular area and terminates abruptly in a rounded, tooth-like shoulder just under the beak; the posterior margin shows a slightly raised elongated, ronghened area for the attachment of the resilium, commencing under the beak and rmming back for some distance within the margin, on its nearly vertical imner surface, so that it is searcely visible in a front view. Ossicle not observed. Ligament very thin, occupying a groove along the posterior margin.

Length, 19 mm .: height. 13 mm .; breadth, 9 mm .; from the beak to the anterodorsal angle, 7 mm .; to the postero-dorsal angle, 12 mm .

One valve (No. 52561 ), station 2492 , N. lat. $45^{\circ} 22^{\prime}$, W. long. 58 $43^{\prime} 45^{\prime \prime}$, in 75 fathoms, 1885.

This species is allied to L. arenosa (Moller) with which it agrees very closely in the character of the external surface and structure of the linge. It differs in its longer, more ovate form, in its more produced anterior end, and in its less swollen umbo.

## Family PANDORID.E.

## CLIDIOPHORA INORNATA, new species.

> (Plate XCV, figs. 5, 6.)

Shell small, much compressed, very inequilateral, posterior end narrowed, somewhat accminate, the right valve flat or slightly convex and the left valve a little swollen. Umbos not prominent; beaks smatl and appressed. The antero-dorsal margin is slightly convex and slopes rapidly to the bluntly romded anterior end; the ventral margin is broadly rounded and slightly prominent, considerably behind the middte, beyoud which it is incurved to meet the posterior rostral angulation: the posterior end is produced into a short, narrow, subtruncated. slightly mpturned rostrim, its lower angle formed by a somewhat prominent, radial rib or ridge, extending from the beak (on the
left valre); the postero-donsal margin is usually slightly concave, lut is sometimes nearly straight, and in some cases decidedly concave, and slopes gradually to the smperior angulation of the rostrum; the ligamental area is narow, deep, and long, extending for nearly the entire length of the dorsal margin, and is clearly defined by a marginal ridge which is sharper on the left valye. In most specimens this valre is marked by a slight, ill-defined groove rmning from the beak to the antero-ventral margin, where it often forms a slight emargination, but is often soarcely discernible, except by the change in the direction of the lines of growth and chancter of the epidermis. The surface of the left valve is covered with inregular concentric ridges and rather meven lines of growth; the right valve usually shows rather regular, concentric undnlations on which are numerous fine, pretty regular, lines of growth; this valve is also usually marked by faint, and rather indisfinct, raliating, impressed lines which are more or less broken and often branched or forked; these are scarcely visible without a lens. Epidermis thin, brownish yellow, usually mostly peeled off in dry specimens, but on the anterior end, in front of the radial groove, it is a little more persistent. ln the left valve the anterior tooth is strong and prominent, with the proximal end the thicker, more elevated, rounded or clavate; distally it is curved and diverges considerbly from the anterodorsal margin; between this tooth and the resilial pit, there is a small rentral tooth only a little elevated. The resilial pit is directed obliquely backward, and its cavity is obliquely upturned, forming a distinct excavation on the inner surface of the posterior tooth with which it is conflnent; this posterior tooth is simply a distinctly thickened and slightly elevated portion of the postero-dorsal margin, which forms the boundary of the ligamental area, it is often, but not always, opposite the position of the resilial pit. In the right valve the anterior tonth is a slightly raised, somewhat eurved ridge on the immer surface of the shell, ruming to the middle of the anterior muscular sear; the central tooth is shorter and much more elevated, most prominent at its imer end; between these two teeth there is an additional, slightly raised, tooth-like ridge; the posterior tooth is abont as long as the anterior, and much more elevated and stouter, its distal end being the thicker and higher, with a distinct angular summit; the obligue resilial pit is excarated ont of its anterior surface. The ossicle is somewhat chongated, curved or crescent shaped. The interior of the shell is only slightly lustrons and shows but little iridescence.

Length of one of the largest specimens, 19 mm ; height, 11 mm ; thickness, about 3 mm .

Found in considerable numbers at twenty-three stations, north of Cape Cod, off Stellwagens Bank, and off Chatham, in 10 to 43 fathoms, 187:-1881.

This species, which is common in the vicinity of Cape Cod, has probably been confomuded, hitherto, with O. Wilineate Say, and C. gonedient Jall. From the latter, which oceurs abundantly in the same
region, it differs in its much smaller size, much less iridesernt interior, straghter postero-dorsal margin, less upturned rostrum, and narrow, or more arcuminate, posterior half of the shell. The hinge also differs in several respects.

## KENNERLIA BREVIS, new species.

(Plate LXXXVIll, figs. 7, u, b.)
Kennerlia glaciulis Temmal, Notice of Recent Add. to Mar. Invert., Pt. 2. Proc. U. S. Nat. Mus., MII, p. 397, 1881; Trans. Conn. Acad., V, p. 567, 1882; VI, p. 277, 18R4.-Dall, Bull. U.S. Nat. Mns.. No. 37. 1. 68, 1889 (in part).

Shell short, sublumate, very inequilateral, obtuse at both ends, slightly narrowed anteriorly. The antero-dorsal margin is short and slopes rather rapidly to the anterior end, where it forms an obtuse angle with the rentral margin which is broadly and nearly evenly romnded, and passes into the rounded posterior margin without angulation, but sometimes with a slightly sintous eurve below; there is also, sometimes, a very slight simosity anteriorly; the postero-dorsal margin is nearly straight. The left valve is rather convex, moderately thick, nearly smooth, with a distinet, narrow dadial ridge rmuing from the beak to the posterior end. The right value is smaller, concave or nearly Hat, lumate, widest behiml the middle, regulaly curved ventrally or faintly sinuate anteriorly; its surface is marked by lines of growth and crossed by radial grooves, of which about ten are rery distinct, while many others, much finer, can be seen with a lens. In the right valre the hinge consists of two small, divergent teeth, both of which are directed posteriorly. The rather thin, elongated posterior one, in a profile view, is obtusely triangular, its highest point distal to the middle; the slender resilinm is attached to this, nearly the whole length of its anterior side, and carries a long, narow ossicle. The cardinal tooth directly under the beak, is much shorter and somewhat thicker, with its highest point near the proximal end which is close to the dorsal margin. There is also a slightly elevated, rather indistinct, anterior submarginal ridge, parallel with the margin, which supports a slender ligamental groove. In the left valve the hinge consists of a snomarginal, thickened, blunt anterior tootl, runuing forward subparallel with the margin, and a posterior snbmarginal thickening or ridge laving the resilinm attached to its anterior side; the $V$-shaped space is relatively very wide and is not divided by any distinct intermediate ridges, such as occur in typieal I'mulorn. The resilim appears to be simple, not divided in a V-shaped form as in the latter genus.

Length of one of the largest specimens, 11.5 mm ; height, $7 \mathrm{mm}$. : thickness, 3 mm .

Found in small numbers at about ten stations between N. lat. $40010^{\prime}$ $30^{\prime \prime}$, W. long. $70 \circ 2 \sigma^{\prime}$, aud N. lat. $3 \mathrm{~T}^{\circ} 100^{\prime} 40^{\prime \prime}$, W. long. $75^{\circ} 6^{\prime} 10^{\prime \prime}$, in 58 to 100 fathoms, $1880-188 \mathrm{f}$.

This species, which is southern in its range. is closely related to the
northern K．glacialis（Leach）with which it was formerly identitied． It is a smaller．shorter，and more inflated speeies，with a shorter and more sloping antero－dorsal margin and a more evenly curved rentral margin，withont the distinct antero－rentral indentation seen in that spectes．The convex valve has a distinct．posterior radial ridge which is faint or lacking in $h$ ．glacinlis．There are also differences in the hinge．in the right valve of the latter the teeth are moredivergent．ete．

Doctor Carpenter．who established the group hennerlia，defined it as ditiering from tepieal Pendore in having an ossicle on the cartilage or resilium．and radial grooves on the right valve．l＇erhaps the simple linear form of the resilimm in Kennerlia and its forked or V －shaped form in true l＇andora（type $P$＇．rostuta Lamarek）may be of more impor－ tance．The intermediate ridge in the left valve of Pamdora fits between the two divisions of the V －shaped resilium．There is also in liennerlia a small．buttress－like projection within the margin．moder the beak． which supports an inwarl projecting portion of the ligament，darker in color than the resilim．

## Family PERIPLOMID．E．

## PERIPLOMA AFFINIS，new species．

## Plate LXXXVII，tig．4．）

Shell thin，fragile，broad ovate，with the beaks behind the middle and with a short，narrowed posterior end．The antero－dorsal margin is broadly convex：anterior end nearly evenly rombled，but slightly produced in the middle；reutral margin evenly convex to the base of the rostral region where it becomes slightly inenrsed；posterior end much narrowed，compressed and produced into a short，blunt rostrum with the edges gaping slightly at the end：postero－dorsal margin nearly straight．sloping rapidly to the angle of the rostrum：a faint diagonal ridge extends to the lower rostral angle，posterior to which the shell is smoother than elsewhere and marked with several faint． radial riblets．The general surface is corered with irregular，meven and often rather faint，concentric undulations．separated by rather wide concave intervals which，like the elevations，are covered by thin， elevated lines of growth．The modulations are most regular on the umbos and become less distinct and more irregular towarl the margin and anteriorly，and show by tramsparency on the interior of the shell． The chondrophore is small．but very prominent，spoon－shaped，narrow at the base and expanded distally，with a nearly round resilial pit． The ossicle is well developed．bent into a crescent shape．and so formed as to fit into the small ronded noteh in the shell margin in tront of the chondrophores．A somemhat clevated submarginal ridge extends forward from the noteh and serves to support the thin ligament：a similar but less prominent ridge extends backward from the chondro－ phores and defines a distinct ligamental groove．

Length of the largest specimens, 13 mm.: height, 10 mm .: brealth, 8 mm .
Three specimens were found at three stations. of Marthas Vineyard, in 100 to 115 fathoms, $1880-81$.
'This species resembles l'. undulutu in sculpture, but the latter is marrower and longer in form, and has a more decidedly longer rostrum; its chrondrophore is shorter and broader, and not so distinctly spoonwhiped distally, while the marginal notch in front of it is relatively mueh smaller.

## PERIPLOMA UNDULATA Verrill.

## (Plates LXXIX, fig. 1; LXXX゙VII, fig. 5.)

I'eriploma nudulata Verrill, Trans. Conn. Acad., VI, pp. 433, 448, 1885.
A few specimens were fornd at six stations between N. lat. $3909^{\prime}$, W. long. $7: 3 \circ 3^{\prime} 15^{\prime \prime}$, and N. lat. $36^{\circ} 42^{\prime}$, W. long. $74^{\circ} 30^{\prime}$, in 541 to 816 fathoms, 1854-1887.

## Family LIMID.E.

## LIMATULA REGULARIS, new species.

Shell small, thin, nearly equilateral, much higher than long, with the hinge-line straight and rather long. Unbos and median part of the shell swollen. Beaks rather prominent, directly incurved. Ligamental area relatively large, elongated, diamond-shaped, with the pointed end extending nearly to the angles of the hinge-margin, with a central, more sunken, short. rhomboidal ligament-pit which, on a separate valve, forms nearly an equilateral triangle. The anterior and posterior ends are nearly equally curved, a little convex, but slightly narrowed where they join the hinge margin and form a distinet obtuse augle; on one side, supposed to be anterior, below the angle the margin is slightly incurved for a short distance, making this angle less obtuse than the other. The rentral margin is nearly evenly romided, forming nearly the segment of a circle. The surface is covered with small, elevated, radial ridges separated by concave grooves of greater breadth; in the mildle of the shell between ten and twelve of the ridges are distinetly higher and thicker; on each side their size diminishes outwardly, so that near the angles of the hinge they become nearly or quite obsolete, the last ones being mere raised, microscopic threads: in some cases smaller ones alternate with the larger ones, so that the total number can not be definitely determined, but fifty or more can often be counted. There is often no very evident median external suleus, such as occurs in several related speces, but the two or three central radii are often, but not always, distinctly larger than the rest. The radii are crossed by very fine lines of growth not sufficiently strong to render them at all nodulose. The inner margin is
distinctly eremulated along the prominent ventral edge, the crennlations corresponding to the external grooves and ridges, but at the ends it is smooth. There is often a distinct, median internal groove, extending fiom near the beak to the middle of the ventral margin, bordered on each side by a distinct raised tidge, sometimes having an additional groove on their outer sides. The hinge-margin is rather thin, nearly straight, and a little excavated or incurved along the ligamental pit; on each side and considerably within the margin there is a small triangular buttress or shelf-like process extending to the anterior and posterior margins as in the allied species, but rather larger than usual.

Length of one of the largest species, 6 mm .; height, 9.6 mm .; thickness, about 5 mm .; length of hinge-margin, 3.6 mm .

A number of separate valves, station 2265, N. lat. $37^{\circ} 7^{\prime} 40^{\prime \prime}$, W. long. $74^{\circ} 3 \bar{J}^{\prime} 40^{\prime \prime}$, in 70 fathoms, 1884.
This species is allied to Limatula subovata (Jeffreys) Smith, ${ }^{1}$ which is distinguished by its shorter hinge-margin, more contracted form, with stronger and higher radial ribs and well-marked median sulcus. It also lacks the incurvature of the margins below the angles of the hinge.

## LIMATULA NODULOSA, new species.

Shell small, nearly equilateral, vertically ovate, narrowed aloove, with a comparatively short, straight, hinge-margin. Umbos prominent, a little compressed. Beaks small, a little prominent, directly incurved. Surface covered with radial ribs which are very fine and even on the anterior and posterior ends, but in the middle region, become much stronger and are rendered nodulose by strongly marked, raised, concentric lines and grooves. The two median ones are much stronger than the others and are separated by a distinct median sulcus. The inner surface is marked by radial ridges and grooves of which the median ones are much the stronger; inner margin crennlated ventrally by the ends of the ribs and grooves. ligamental area diamond shape with a small, short, rhomboidal ligament-pit in the middle. The hinge-margin forms an obtuse angle at each end, the two nearly or quite equal; internal buttress well developed with the imer margin regularly curved and contiunons across the middle, so as to thicken the hinge in this part.

Length, 4.5 mm .; height, 7 mm .; thickness, about 4 mm .; length of the linge-margin, 2 mm .

A single valve, among Foraminifera, at station 2385, N. lat. $28^{\circ} 51^{\prime}$, W. long. $88^{\circ} 18^{\prime}$, in 730 fathoms, 1885.

This species agrees with L. suborata (Jeffreys) Smith almost completely in size and form, but differs very decidedly in the strong, nodulose, radial ribs which cover the middle portion of the shell.

[^6]
## LIMATULA HYALINA, new species.

Shell small, thin, translucent, vertically ovate, somewhat oblique, and produced postero-ventrally. Hinge-line straight, rather short, forming a well-marked angle at each end owing to the outline of each margin becoming somewhat concave below. Beaks small, acnte, incurved. Umbos prominent, smooth, beyond which the shell is covered with numerons, clearly defined, rather sharp radial ridges, separated by wider concave intervals; from twenty to twenty-five of the radii can be easily counted; toward the posterior margin they become faint and indistinct, while the extreme margin, on both sides, is smooth. The anterior margin is broadly romded and slopes backward below the middle; the posterior margin is nealy straight or eveu a little incurved in its upper half, but becomes slightly convex below; the ventral margin is evenly romed and the edge is slightly scalloped by the radial ribs and furrows. There is no distinct median sulcus or larger tibs. The ligamental area is rather short and broad with a relatively large and thick central ligament which occupies a distinctly excavated pit in the hinge-margin.

Length of one of the largest specimens, 4.5 mm .; height, 7.5 mm ; thickness, 3 mm .

A number of live specimens, among Foraminifera, stations 2367 to 2374, N. lat. $29^{\circ}$ +, W. long. $85^{\circ}+$, in 25 to 27 fathoms, 1885.

This species somewhat resembles Limutula confusa Smith, which was also taken in the north Atlantic and West Indian areas, in 450 to 1,450 fathoms. Our species is, however, more compressed and more oblique, and the radial ribs do not extend to the extreme margins as in the latter. The hinge-margin is also relatively shorter and the ligamental area larger, so that the beaks are more separated.

## Family PECTINID.E.

In this family the classification adopted is that proposed by the senior anthor in a recent paper on the group. ${ }^{1}$ We give here a brief abstract of the existing genera and subgenera therein described. For fuller discussious of the characters and interrelations of these groups and illustrations of typical species of most of them, reference shond be liad to that article.

In the following synopsis the generic groups are arranged in chronological order, without regard to their zoölogical affinities.

[^7]
## PECTEN Müller, 1776.

> I'ecten (1st section) Klean, $1753+$ Tola.
> P'eten Mëller, Prod. Zö̈l. Dan., 1776 (pers).-DaCosta, 1778.—Bolten, 1798 (restricted).-Cuvier, 1798.-Lamabick, Syst., 1801.-Verrila, Tralis, Comm. Aead., , pp. 56, 84, 91, 1897.
> Jeniru Shhtmacher, 1817.-Dall, 1886 (pars).-Fincher, 1887.
India, Cretaceons Pelecypod Fauna, III, p. 426, 1871.-Zıttea, 1 1881.
「ola + Janira Cimend, 1862.

## Type.- Pecten maximus (Limmens).

Since Bolten, in 179s, definitely restricted the mame l'perten to this group, his restriction has precedence over that of schumacher.

The shells are generally large and heavy, and the valves are very mequal, even when very young. The right valve is strongly convex with a large and much incurved umbo and beak, while the left valve is that or evell concave. It is usually smaller than the right, and shuts elosely inside of its scalloped margin, and its umbo is nearly or quite obsolete. The aurieles are of moderate size and not oblique, and in the right valve they are strongly convex or excurved in the middle. This valve has a simmous, excurved byssal noteh, with obsolete pectinidial teeth. The surface of both valves has strong radial ribs interlocking at the margin. Internally there are angular, thickened. and fluted radial ribs opposite the external grooves; these ribs become more prominent and bicarinate or fluted near the margins.

## AMUSIUM Bolten, 1798.

Amusium Bolten, 1798.-MUHLFELDt, 1811.-SUHUIACHER, 1817.--WOOWARD, 1×66.—1)all, 1886.- Vehrill, Trans, Comm. Acad., X, 1p. 57, 40, 92, 1897.
Amissium H. and A. Adadis, 1858 (pars).-Stoliczía, Mem. Geolog. Survey of India, Cretareons l'elecypod Fanna, III, p. 426, 1s71.-Fraciner, 1087.Zittel, 1881.
Pleuromertia SWans, 1840.-Ciienu, 1862.

## Type.-Amusium plewronectes (Linmans).

In this very distinct genus the shell is romd, thin, nearly smooth, and strongly compressed. The surface is often polished, sometimes lightly radially striated, never strongly ribbed. The margins are simple and thin. The valves may be a little unequal in convexity and usually differ in color and somewhat in senlpture. The valres come together ventrally, but usually gape at both ents. The anricles are small, symmetrical, nearly equilateral, often with lateral crure; the byssal notch is small or absent, pectinidial teeth nearly or quite abortive. The arlult probably has no byssus. Hinge-plate simple. Interior of valves strengthened loy a number of raised divergent ribs, or lira, independent of any external senlpture.

## CHLAMYS Bolten, 1798.

 (pars).
Perten Schumacher, 1817 (restricted).-V'elrill, Trans. ('onn. Acad., N, pl'. 58, 8!, 91, 1897.
 TEL, 1 ®881.
I'ceten stoliczka. 1871 (restricted).
Type.- ('hlamys islandica (Miiller).
The original type of this genns is identical with P. islamticus (Miiller). Therefore this should be adoped. without puestion, as the true type, as has heen done by Fischer and others.

The typical species of chlamys are high, rounded, somewhat oblique, nearly equivalve shells, with large inequilateral and oblique auricles, a large byssal notch, and several pectinidial teeth. The surface is strongly radially senlptured, with both primary and numerous interpolated ribs, increasing in number with age. The ribs are generally crossed by concentric sculpture, often forming rough, scale-like projections. The margins are scalloped and the shell closes rather tightly except at the byssal area. The inner surface has ribs and double flutings, corresponding to the extemal grooves and radii. The hinge-plate has generally two slightly divergent ribs on each end.

## PALLIUM Schumacher, 1817.

P'ullium Schumacher, 1817.-H. and A. Adans, 1858.-Chent, 1862.-Stoliczka,
1871.-Zittel. 1881.-Fincher, 1887.-Verbill, Trams. Comi. Acad., X, Pr.
59, 89, 91, pl. xxi, fig. 4, 1897.
Ientipecten Rippel, $1 \times 35$.

Type.-Pallium plica (Linnens).
The special feature of this very distinct gromp is the dovelopment of several (usually three) well-marked, nearly transverse, blunt teeth, alternating with distinct pits on each end of the hinge-plate. The shell is elevated, rather thick, with extermal, large, obtuse or rounded rartial ribs or corrogations, and with internal, angular, double or bicarinate ribs opposite the external grooves, near the margin. The auricles are small, but high. The hinge-teeth are marked with distinct cross lines.

## HINNITES Defrance, 1821.

Hinnites Verhille, Trans. Comi. Acal., X, pp. $59,89,91,1897$.

## Type.-Hinnites rortessi Defrance.

Shell free and murh like Chlamys, when young, but later in life it becomes attached by the right valve and irregnlar.

HEMIPECTEN Adams and Reeve, 1849.
Hemipecten Verrill, Trans. Com. Acad., X, pp. 60, 89, 91, 1897.
Type.-Hemipecten forbesianus Adams and Reeve.
This group includes suecies with thin, irregular shells attached by the right valve, like Mimites, but the attachment is effected manly by a permanent modified byssms. The posterior auricles are nearly obsolete. The byssal noteh becomes irregular and nearly inclosed, as in Anomia.

PSEUDAMUSIUM H. and A. Adams, 1858.
P'seudumusium (pars) H. and A. Adams, 1858 (after Klein).-Chent, 1862.—'tohimka, 1871.-Zittel, 1881.—Fischer, 1887.—1)all, 1886 (pars).-Vemille, Trans, Conn. Acad., $\mathrm{X}, \mathrm{pp} .60,90,92, \mathrm{pl}$. xvil, figs. $8,8 a, 1897$ (restricted).

## Type-Dsemamusium exoticum (Chemnitz, Lamarek).

The typical species of this group have nearly smooth, round, symmetrical, closed shells with well defined, small, straight, obtuse-angled auricles. The valves are nearly equal and have nearly simple, even margins. The external sculpture consists of small radial stria or riblets, without strong angular ribs and grooves, and it may differ on the two valves. Some of the species show the fine divergent "camptonectes scupture" on one or both valves, especially when young. The margin is not sealloped, or but faintly so, and there are no definite internal ribs. The hinge-plate has usnally but one longitudinal fold on each end which is feeble and nearly parallel with the margimal ligamental groove and is usually cross-lined. The byssal notcll is small and the pectinidial teeth vary from one up to five in number, or sometimes may be lacking.

CAMPTONECTES Meek, 1864.
C'amptonectes Мeek, 1861.-Stoliczka, 1871.-Zittel, 1881 (type, arematus Golit-finss).-V'erhill, Trans. Comn. Acad., X, $\mu \mathrm{p}$. 62, 90, 91, 1897.
Type.-C'amptonectes lens (Sowerby).
Shell subovate, plain, not eorrugated, and without strong radial ribs; margin nearly plain. Valves subequal. Auricles nuequal; byssal notell well developed. Surface of the shell covered with fine, obliquely divergent, curved, cremlated or vermiculated riblets with intervening, narrow, punctate grooves.

The curions vermienlated senlpture is not peenliar to this division, lont is more or less obvions on the shells of some species of Pseulamusimm, and on speeies of several other groups, both with and without radial ribs. It is a stmetural feature that runs obliquely across the rilos and grooves. Most of the species are Mesozoic fossils.

The recent Pecten striatus and P. tigriuns Lamarck, of Enrope, apparently belong to this group, and $l$ '. teste might also well be referred to it. The latter is one of the types of Palliolum which might well be regarded as a section of this genus.

## LYROPECTEN Conrad, 1867.

Liropecten of sereral later authors.

## Type.-- Lyropecten nodosns (Linniens).

Shell large and strong, corrugated, with large, fluterl, and usually norlose, primary radial libs, which do not increase in mumber, and with coarsely scalloped margins. Valves somewhat unequal. Ami cles of medium size, mequal. Hinge-plate with several, usually there, oblique, divergent ribs on each end. This is one of the liest defined groups, and may be regarled as of generic valne. It is allied to I'allium.

## PROPEAMUSIUM Gregorio, 1883.

Propamasimm (subgenns) Jall, Bull. Mns. Comp. Zaiil., XII, P. 210, 1886.— Fiscuer, 18ヶ7.-(gemus) Verribl, Trams. Conn. Acal., X, p1. 6t, 90, 92, pl xx, fig». 5-9, 1897.

Type.-Propamusium inequisculpta. (Tiberi) = Propeamusium fenestratum (Forbes).

This gromp is allied to Amusium. It includes small, mostly deep-sea species, with thin, romnder shells, having the valves mequal in size and sculpture; the lower and tlatter one is concentrically grooved, and usually turns un at the thin margin to meet the upper valve, as in Cyclo. pecten. The upper valve may be cancellated or radially senlptured. When full grown there are several well-formed, raiserl, internal ribs; these may be absent in the young.

This division difiers fiom Lmusium in the sculpture of the valves and in having the auricles and byssal noteh well developed.

The species closely resemble those of Cycloprecten; the only obvious difference in the shells is in the presence of internal ribs.

## PALLIOLUM Monterosato, 1884.

Pa7holum (subgemus or sertion) Verrall, Trans. Conn. Acad., x, pl. 65, 90, 91,

Types citerl.-Palliolum testre (Bivona) and Palliolum ritroum (Chemnitz).

This group is separated from Psentemusium H. and A. Adams, and can scarcely he distinguished from Cumptonectes by any known characters.

The two species named by its anthor as types agree in having thin, romuded, nearly equivalved shells, with the posterior auricle poorly developed, and with fine camptonectes sculpture on both valves, with small radial riblets, and usmally with rows of small scales. The margins are plain and come evenly together, without tlattening.

## 压QUIPECTEN Fischer， 1887.

## Type．－Equipecten operenleris（Limners）．

Shell broady romuded，with the valves nearly equal and symmetrical． Auricles well－formed，angular；hyssal noteh well－developed．The senlp－ ture consists of a moderate number of large and nearly equal primary radial ribs，which increase in size，but are not mueh increased in mum－ ber with age，by the interpolation of new ones．Internal ribs wr flatings correspond to external grooves，but each one is bicarinate or donble，especially near the margins．Hinge－plate with one or two slightly divergent ribs at each end，often crossed by strong transverse incisions．P＇ectinidial teetla abortive in the type，but present in most species．The foot of the type species is subcylindrical，well－dereloped， with a byssal fissure and a terminal，deeply bilobed＂scooped－shaped＂ disk，which can be expanted．In ，D．irrations ${ }^{1}$ the foot has a similat structure，but the terminal disk appears to be smaller．

## PECTINELLA Verıill， 1897.

Type－V＇ectinella sigsbei（1）all）．
Shell small．thin，swollen，nearly smooth，with convex and sliwhty muequal valves．Auricles very unequal，oblique，the anterior larger， with a deep byssal noteh in the right value，but withont pectinidial teeth：posterior auricle small．The surface is smooth except for fine lines of growth．Camptonectes sempture is not present．The texture is not hyaline．

The only known species is I＇ectinellu sigsbei（Dall）${ }^{2}$ which was taken by the Blake Experdition in the Went Indies，in Lis tathoms．

## LISSOPECTEN Verrill， 1897.

 1ふ0

Type．－Lissopecten hyalimus（Poli）．
Shell slightly inequivalve，broadly rombled，not obligme，thin，trats lucout，nearly smooth．The external sculpture consists of fant，nearly obsolete radial ridges and obsenre riblets，but one or both amricles may have a more or less cancellated scolpture．The interior scupture con－ sists of very distinct，simple．raised ribs．Auricles angular，Well－devel－ operl．Byssal notch derp）．Peetinidial teeth prominent．Margin not sealloped，nearly phain and simple．

[^8]Althongh this group agrees with Amusium in having internal ribs without corresponding external grooves, it seems to be allied rather to ('hlemy/s. It may be regarded as a division of the latter in which the extermal radial ribs have degenerated.

## LEPTOPECTEN Verrill, 1897

TYpe.-L"ptopecten monotimeris (Comrad).
Shell thin, tramslucent, oblique, broadly rommed. with strong, rommed radial ridges or folds. like cormgations, which appear in reverse on the interior surface. The intermal ribs are mot angulated by a deposit of shell, nor distinctly thickened. Margin with broad sallons: The exterior surface is covered with fine divergent camponectes sompture, both on the ribs and intervals. 'The ribs do not increase in number with age but berome broader and more Hattened. Auricles laree and broad, thin, corrugated. Byssal noteh large and deep. Vectinidial teeth prominent. Hinge-plate thin and but little differentiated. Cindinal ridge thin and small, close to the ligament. crossed by tine incisions.

## PLACOPECTEN Verrill, 1897.

## Typre-Plucopecten clintonins (Say).

Shell hare, compressed, broally rommed, rather thin, with simple shanp edges, meeting evenly rentrally, but gaping considerably at both ends. expecially when adult. Talses only slightly mequal in form, the right one being a little Hatter, but they differ in color and somewhat in semptme, the right one being smoother and paler. Both have fine radial lines or riblets, and they have vermiculated divergent riblets when young. Auricles small, symmetrical, nearly equal. Tiyssal notch small, simple. l'ectinidial teeth generally obsolete, except when young. No internal ribs. Imner smface often with more or less pearly luster amb a crystalline structme. Hinge-plate with two feeble, slightly divergent ribs on each end, crossed by fine transverse incisions. The toot is well developed, oblique, slighty narrowed distally and enlarged at the end, where it is divided into two lobes by a rather deep, oblique, longitudinal fissure, so that the lobes can be spreat apart or closed at will, thins resembling somewhat the foot of Ledirle. Towarl the base, on the anterior side, there is also a short, deep byssal slit, terminating at a prominent tuberele abont the middle of the firont side.

## CYCLOPECTEN Verrill, 1897.

Cyelopecten Vrrrim, Trans. Comb. Acad., X, pp. 70, 90, 92, pl. xit, fig. 1 ; pl. xix, figs. 1-4, 1897.

Types-Cycloperten pustulosus Verrill and Cycloperten imbrifer (Lovíil).

Shells thin, rommed, scarcely oblique, with syumetrical anticles and simple margins. The two valves are mulike in sculpture. The right valve is a little flattened and upturned at the Hexible margin, so as to fit tightly against the upper valve. The thin lower valve has, in the typical species, regular, thin, elevated, concentric lamella, which aid in the adaptation of the erge to that of the upper valve; the margin is usually flattener or bevelled. The upper (left) valve is radially sculptured, rarely smooth; it usually has radial rows of arched seales, pustuies, or points, and also concentric raised lines; it is sometimes cancellated. No radial ribs, nor interlocking points at the margin. Auricles well-dereloped, subequal, angulated and well defined at both ends; byssal noteh well-defined; few or no pectinidial teeth. Cardinal folds single, rather feebly developed, often eross-lined. Eyes few. Byssus small, and of few threads.

This genns includes a large number of small species, mostly from deep-water.

$$
\text { HYALOPECTEN Verrill, } 1897 .
$$

Type-Myalopecten umlatns. Verrill.
Shell compressed, thin, hyaline. Valves nearly equal, with eoncentric undulations or corrugations, affecting the entire thickness; margins simple; seulpture none, or consisting of fine radial lines on one or both valves, without camptonectes seulpture. Hinge-plate thin and nearly plain; auricles well-developed, unequal; byssal notch distinct.

For the possible relations of this group to the Mesozoic genns, Ayncyclonema, see the original article.

The species recorded are as follows: $M$. Milectus Verrill and Bush, from 1,S13 fathoms, off Marthas Vineyard; $H$. firagilis (Jefireys), from northern Enrope and the Arctic Ocean, and off the Cuited states coast, in 578 to 1,525 fathoms; $M$. undatus Verrill, ofir the United States coast, in 1,423 fathoms; and H. pudicus (Smith), off Marion Island, in 1,375 fathoms.

$$
\text { PARAMUSIUM Verrill, } 1897 .
$$

Paramusium V'errill, Trans. Comı. Acad., X, pp. 72, $90,42,1897$.
Type.-Paramusium dalli (Smith). ${ }^{1}$
Shell thin, romuled, much compressed; valves nearly equal; sculpture nearly obsolete, different on the two valves; the lower valve with concentric undulations. Auricles verysmall, equal. Byssal notch and

[^9]peetinidial teeth obsolete. The shell has a prismatic structure. Internal lirse and auricular crure well-developed.
The structure of the animal was described by Mr. Dall as very different from that of typical Amusinm. According to his deseription it las a single pair of gills, with long, simple, separate filaments. The foot is slender, with a byssal groove; the end is mucl enlarged, with an oblique, expanded, concave terminal disk, striated within. No labial palpi. Ocelli without pigment.

A specimen, well preserved in alcohol, examined by the, had two rows of long, slender, reflected gill-filaments, as usual in this family. They were attached to a broad basal membrane, with a free, lanceolate, posterior portion. Two pairs of broad, foliaceons, incurved palpi, tinged witlı dark brown. Those of the anterior pair are united into a hood over the mouth; the others are smaller, curved inward, somewhat lanceolate at the tips. No ocelli could be found. The pallial tentacles are all in one row, numerons, of varions sizes; from four to six large ones, with as many alternating small ones, correspond to each larger mudulation or seallop of the mantle-margin. No guard-tentacles. Museular pallial border is broad, thickened, radially striated, forming a ridge, as preserved, but not tentarnlated. Free portion of rectum long and sleuder.

A synopsis of the Pectinide was recently published by Dr. Frederico Satceo.

He recognized three genera: Chlamys, A mussinm, and Pecten, with the same types given by Verrill. Under Chlamys he gives nine subgenera. Of these, four-Chlamys (restricted), IInnites, .Equipecten, and I'allio-lum-correspond with the groups of the same name given by Verrill; Felipes Locard (type, pesfelis L.), I'ephum Bucquoy, Dantzenberg, and Dollfus, 1889 (type, inflerum I'oli), Macrochelmis Saceo, 1897 (type, lutissimu Brocehi), Flexonecten Saceo, 1897 (type, flexuosus Poli), Lissochlamis Sacco, 1897 (type, excisa Bromn), are additional to those given by Verrill.

Under Amussinm he has, besides the typical gronp, four snbgenera. Of these, two are new-Parramussinm Sarco, 1597 (type, duodecimlamellatum Bronn), V'ariamussium Saceo, 1897 (type, cancellutum Sehmidt). The two others are Propcamussium and I'sendamussium.

The thee new subgenera of Pecten are Amussiopecten Saceo, 1897 (type, burdiyulensis Lamarek); Ö̈pecten Saceo, 1597 (type, rotundutus Lamarek); and Flabellipecten Sacco, 1897 (type, Atubelliformis Brocehi).

[^10]
# CHLAMYS BENEDICTI Verrill and Bush. 

(Plate LNXNIV, figs. 1, 2.)
 91, $1 \times 97$.

Shell small, higher than long; anterior auricle much larger than the posterior, with a deep byssal noteh in the lower or right valve. The dorsal margin is straight amd but slightly oblique: the posterior anticle in the right valye is decidedly angular, with its onter end slightly incurved and semated by the termination of the ratlial ribs; the anterior anricle is considerably prolonged, angulated at the upper corner, obtusely romnded at the end and deeply motched where it joins the main shell; it has fom strongly marked radiating ribs, besides the dorso-marginal fold; below these there is a slightly concave space corresponding to the byssal noteh; on the body of the shell there are from four to seven sharl serrations along the lower margin of the notch. In the upper valve the anterior anricle is broad and decidedly angular, the dorsal and outer margins forming less than a right angle; its surface is covered with five or six strong radiating ribs decussated by more numerons, finer, eoncentric: rased lines. The anterior and posterior margins of the body of the shell slope abont equally and form an acute angle; the ventral margin forms a regular semicircular curve. The entire surface in both valves is crossed by strongly raised, rather close, radiating ribs separated by rathor wide, deep grooves and are decussated by regular, raised, concentric lines, which are searely apparent on the ribs, except on very young shells, but there are rather strong, elevated, spine-like points arranged along the ribs in pretty regnlar, roncentric lines, especially near the margins; these become higher and more pointed anteriorly and are frequently nearly obsolete in the middle portion of the lower valve; the ribs project at the margin as blunt points or serrations; on the inner surface there are radial grooves corresponding to the external ribs. The hinge-margin is thin, with a slender ligamental, submarginal groove and a small, triangular resilial pit in the center. The color is variable; the single valve from station 2571 is uniform lemon yellow; those from the other locality are chestnnt or reddish brown and variegated with paler and sometimes white blotehes.

Length of the largest specimen, i. 5 mm ; height, 6 mm ; length of dorsal margin, 4 mm .

A few live young specimens, among Foraminifera, stations 2369 to 2374 , in 25 to 27 fathoms, and a single valve, station 2571 , in 1,356 fathoms, 188\%.

This species is a typieal Chlamys, allied to C. varia of Europe, but when compared with young of that species of the same size the radial ribs are fomm to be fewer and coarser, and there are other differences which remder it probably that they are distinct. It differs from the yomg of ('. islamdica in the number of ribs and shape of the anricles.

It is probable, however, that it grows to a much larger size than any of the specimens obtained.

It is named in honor of Mr. Tames E. Benedict, for several years zoölogist in charge on the steamer Alhatross, throngh whose "are and great interest so many small species were brought to light.

CHLAMYS COSTELLATA Verrill and Bush.
(Plate LXXXVI, fig. 6.)
Chlamys costellata Verrill and Bush, in Verrile, Trans. Conn. Acad., A, ill. Th, 91, 1897.

Shell small, thin, translucent, bhish white, covered on both valres with continuous, elevated and somewhat thickened, well-separated, radiating riblets, of which there are more than thirty in the left valve of the largest example. Length of the shell considerably less than its height. Dorsal hinge-margin elongated, especially on the auterior end. In the right valve the anterior anricle is considerably elongated, obtusely rounded or subtruncated at the end, with a wide, angular byssal noteh beneath it, having two or three pectinidial teeth: it has a broad, smooth, angular area next the body of the shell, above which there are three well-marked, angular, radial ridges, separated by wider concave interspaces; the posterior auricle is small, triangular, the outer corner forming a little more than a right angle, and the posterior margin nearly straight, without any distinct notch. The dorsal margins of the body of the shell are nearly straight and diverge at less than a right angle; the ventral margin is pretty evenly rounded, a little produced in the middle. The beak is small, acute, appressed, and does not project beyond the margin. The radial ribs are very distinet, clean cut, thickened, rounded at the summit, separated by nearly smooth intervals, two or three times as broad as the ribs themselves; the ribs increase regularly in width from near the umbo to the margin; a few intermediate ridges commence near the margin. The left valve is badly broken; it is, however, somewhat more convex than the other, and the radial ribs are crossed by numerous concentric striations giving them a finely cremulated or beaded appearance; the anterior amricle is broad, triangular, the onter end slightly romded, with a slight incurved noteh below; it is crossed by about six small, radial ribs, similar to those on the body of the shell; raised lines of growth also occur at irregular intervals. Inner surface smooth and lustrous, showing the grooves correspouding to the external ribs and also a very distinct microscopic structure, but it is destitute of radial lire. Internally, the hinge-margin is thin and narrow, with a sharply impressed, submarginal groove on each side; the resilial pit is excavated in the margin of the hinge itself; the anterior auricle has internal grooves corresponding to the external ribs.

Length of the largest specimen, fimm. ; height, 6.5 mm.
Three live specimens, at two stations, off the Grand Banks, in tif to 72 fathoms, 1885-86.

## (Plate N(IVIL, fig.!.)

 80, 92, 1897.

Shell small, thin, tiagile, strongly mudulated, slightly oblique, with the ventral margin broadly rounded, dorsal margin straight. In the right valve the anterior auricle is rather narrow, elongated, with a deep angular notel beneath; the posterior anticle is shorter, with a prominent dorsal angle which is less than a right angle, owing to the emargination of the posterior end. In the left valve the anterior anicle is broad, with its posterior end nearly rectilinear, and forms a right angle with the dorsal marein; the posterior auriele has a slightly prominent dorsal angle and posterior emargination as in the right valve. The beaks are a little prominent and project somewhat above the dorsal margin, more in the upper or left valve. The surface in both valves is covered with broad and rather regular undulations, which are most prominent in the left valve, and are crossed by regular, well-spaeed, thin, raised, radial lines, which become fine and more crowded at the ends of the valve; they are nearly obsolete in the right valve, being represented by mieroscopic strise. In both valves the anterior aturiele is marked by several fine, rough, radial ridges which are stronger and more nnmerous in the left valve. The interior is strongly mudulated, and the left valve is marked by distinct, radial grooves. Resilium sinall, cential. Color yellow, or dirty white.

Length, $s$ mm.; height, the same.
One live, inperfect specimen (No. 59539), station 2570, off Marthas Vineyard, in 1,s13 fathoms, 1885.

This species is closely allied to Myalopecten frogilis (.Jeffreys) and resembles very nearly his figure, ${ }^{1}$ which probably represents a species distinct from the original type described by him, and may be identical with our shell. The latter differs decidedly from the original descrip tion of $I I$. frogilis. Moreover, we have ohtained from several stations a shell of similar size which appears to be the true firagilis, ${ }^{2}$ as it agrees closely with the description. Hyuloperten purlicus (Smith) from east of Marion Islami, in 1,375 fathoms, is a elosely related species, as is also Hyalopecten mudatus Velrill.

These four species agree in having the valves thin and translncent and seulptured with distinct concentric undulations, while the radial sculpture does not form strong ribs. They seem to be related to the genns or subgenus Symeyclonemu Meek, which was based on a cretaceons speries and has not hitherto been reported as still living. But the exact characters of the typical fossil species are not yet known.

[^11](Plate LXXXV, fig. 7.)

Pecten grantandicus Sowerby, Thesamms Conchyliornm, P't.if, p. 57, pl. xili, lig.
 Mig. Nat. History, p. 231, 1877.
I'ectell gromandicus (i. O. Sars, Moll. Reg. Aret. Norveg., p. 23, pl. 2, figs. 4, $a-c, 1878$.
 Check-list, p. 26, 1879.
I'ceten grönlandicus Vererill, Trans. Comn. Acall., V, p. 581, 1882.
P'ecten groulandicus Locard, C'ampagne du Candan, Amales de l'Ťniversité de Lyon, p. 217, 1896.
Camptonctes !frenlamdiea Terrill, Trans. Comn. Aeal., ג, pp. \&̌2, 91, 1897.
The shell is rounded, inequivalved, very thin, hyaline, nearly smooth, often with a violet iridescence when fresh. The left valve is covered, eren from the nuclens, with fine microscopic camptonectes sculpture, in the form of thin, raised, divergent riblets, more or less irregular and wavy, most visible by translucency. The left valve sometimes has, also, fine radial strie and delicate lines of growth. The margins are thin and smooth. that of the right valve turns up a little against the other, which is larger, and the valves close very tightly, so that anteriorly there is searcely any visible gape, even at the byssal notch or at the end of the auricle. The byssal notch is well-marked and the peetinidial teeth are small and few. The byssus is probably very slender. The auricles are not oblifue and are nearly equal. The hinge-plate is very thin; the single longitudinal ridge is scarcely visible.

A row of six or seven ocelli can be seen through the shell in alcoholie specimens.

A few live specimens were dredged by the United States Fish Commission at four stations, off Newfoundland Banks, in 130 to 224 fathoms, between N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ} 35^{\prime} 30^{\prime \prime}$, and N. lat. $44046^{\prime} 30^{\prime \prime}$, W. long. $59055^{\prime} 45^{\prime \prime}, 1854-1856$. It is also known from the Aretic Ocean and off northern Europe.

## CYCLOPECTEN NANUS Verrill and Bush.

(Plate LXXXV, figs. 2-4.)
Fyelopecten momus Verrill and Bush, in Verisill, Trans. Com. Acad., N, pp. ©5,

Shell small, the breadth and height abont equal, the valves nearly equal in size and convexity. Dorsal hinge-margin rather long and straight; auricles relatively large and broad, both ends in the left valve subtruncated or a little convex and forming nearly a right angle with the dorsal margin, and having a small incurved noteh, well differentiated from the body of the shell. In the right valve the anterior auricle is narrow, somewhat more elongated, obtusely rounded at the
end, with a sharp, angular, byssal notch beneath it, separated from the body of the shell ly a narrow groove. The dorsal margins of the body of the shell are nearly straight and form more than a right angle; the ventral margin is broadly rounded, nearly semicircular, forming a very obtusely romded angle, where it joins the dorsal margins. Umbos a little prominent, with a small, smooth, rather acute, incurved beak, which projects a little above the hinge-margin. The surface of the left valve is everywhere thickly covered with fine, almost microscopic, radiating strian, which become a little more distinct on the anterior auricle: slightly raised thin lines of growth are often very distinct on some parts of the shell, especially on the anterior auricle, where they become closer, more regular, and often produce, in crossing the radial striations, a quite regular, microscopic deenssation; the sculpture on the posterior anricle is sometimes similar lout finer, although in many specimens the surface is nearly smooth or marked only by very fine radial stria. The right valve is less conver than the left (its ventral edge does not quite reach that of the opposite valve), the umbo is less prominent, the beak less acnte, and scarcely projects beyond, and often falls short of, the hinge-margin; the inerfuality is less marked than in most of the allied species. The body of the shell in this valve is smooth, except for very fine, irregular lines of growth; on the anterior anricle there are from three to six, or more, distinct radial ridges, ronghened by conspicuons lines of growth; the margin below the byssal notch is entire, without pectinidial teeth; the posterior anricle is nearly smooth. The internal hinge-plate is thin in the middle, but relatively broad on each anricle, and is crossed by numerons fine, well-marked, transverse striations; these are much more conspicnons than in any of the related species, whether young or old. The resilial pit is small, rounded, situated just muder the beaik. The inner surface is smooth and glossy, although in fresh specimens the external iadiating lines show throngli ly transparency. There are no internal lira.

The ground color of the right valve is yellowish or grayish white, with more or less numerous light yellowish brown and reddish brown spots or blotches, and sometimes with irregnlar patches of opaque white; the right valve is white, sometimes with a few yellowish brown spots. Some specimens are nearly destitute of spots.
length of one of the largest specimens, 7 mm .; height, 6 mm .; dorsal hinge-margin, + mm.

It has been taken in considerable mmbers, live and dead, at three stations between N. lat. $377^{\circ} 7^{\prime} 40^{\prime \prime}$, W. long. $74^{\circ} 35^{\prime} 40^{\prime \prime}$, and N. lat. $35^{\circ}$ 42', W. long. $74^{\circ} 54^{\prime} 30^{\prime \prime}$, in 43 to 13 ² fathoms, $1884 .^{2}$

Althongh very small, this species seems to be adult. It is so distinct from all other species of our coast that a detailed comparison is nunec. essary. it resembles the romg of $I^{\prime}$. clintom more than any other native species, but a comprarison of specimens of the same size shows marked differences. -

# CYCLOPECTEN LEPTALEUS Verrill. 

(Plate LXXXV, fig. 1.)

Mr. Dall has expressed a doubt as to this species being distinct from Pecten imbrifer Lovén, therefore a very much enlarged figure of the shell is here introduced for comparison.

In addition to the published description, it shonld be stated that the concentric lines are somewhat thickened and elevated, even where thimiest, and that the beaded character is quite mulike anything found on C. imbrifer, or allied species. The beads are closely arranged, elliptical in form, and most elevated at the center, the elevation heing often greater than the diameter; the snmmit is smooth and glassy, so that when viewed from above, under a lens, they often appear to have a central cavity. The radial lines are comparatively very thin and delicate, and not visible, except when considerably magnified. The beaks are more acute than in $C$. imbrifer, and the nueleus smaller and smoother.
'Two live specimens, station 2109, off' Cape Hatteras, North Carolina, in 142 fathoms, 1883.

## CYCLOPECTEN PUSTULOSUS Verrill.

## (Plate LXXXV, figs. 5, 6. 10, 11.)

Pecten pustulosus Verrill, Amer. Jonrn. Science, V', p. 14, 1873; Trans. C'onm. Acad., III, 1. $\mathbf{2 0}$, 187.

Cyclopecten pustulosus Verrill Trans. Conn. Acad., X, pp. 70, 83. 92, ju. xix, figs. 3, 4, 1897.
This species has been referred to Propeamusium hoskynsi by Jeffreys, and to Pecten (Cyclopecten) imbrifer by Dall. It never has the internal ribs, like the former, which it resembles in sculpture. From the latter, as originally described by Lovén, and redescribed and tigured by G. O. Sars, it differs especially in the character of the ornamentation of the left valve. The Scandinavian form, according to these authors, has the vesicles much less erowded in each radial row and subconical and mucronate in form; while in ours they are usually
elosely crowded, often even in contact in the radial rows, and in form either romuded or elliptical with the longest diameter in the direction of the concentric lines, with the summit evenly rounderl, showing no tendency to the subconical or mucronate form. When perfect they resemble small blisters with the surface roughened or minately gramulose under the microscope; when broken or worn off, as frequently happens, the basal part remains in the form of a semicirenlar or semieliptical, imbricated, arched scale, usually considerably elevated above the smrface and comeeted by very delicate concentric raised lines. The surface of the anterior auricle of the left valve is roughened ly close, elevated, concentric lines, and from four to six well-marked radiating ridges or ribs, upon which the concentric lines form regular elevated arched projections, often so crowded as to be imbricated; in some young examples, like the one figured, the concentric lines on the amricle are less crowded and only two or three of the radial ribs are developed; in such examples the vesicles on the body of the shell are relatively fewer, larger, more rounded, and much less crowded in the radial series. In some specimens the posterior margin, below the auricle, is nearly smooth or marked only by the fine lines of growth, while in others, especially larger specimens, this region is covered by rather sharp grammes, some of which, toward the ventral margin, change to pointed seales aranged in crowded radial rows. The raised concentric lines on the right valve are generally more or less appressed and sometimes imbricated; toward the ventral margin some of them show very fime microscopic crenulations, which are much less distinct than on C. imbrifer, as figured by Sars.

This species is distinct from that figured by Mr. Ball under the name of C.imbrifer. His specimen apparently belongs to the following species.

Several live and dead specimens, at eleven stations between N. lat. $44^{\circ} 34^{\prime}$, W. long. $56^{\circ} 41^{\prime} 45^{\prime \prime}$, and N. lat. $39^{\circ} 48^{\prime} 30^{\prime \prime}$, W. long. $70^{\circ} 54^{\prime}$, in !9!2 to 547 fathoms, $1872-1885$.

CYCLOPECTEN SUBIMBRIFER Verrill and Bush.
(Plate LXXXV, figs. 8, 9.)

I'ecten (Psendamusinm) imbrifer Dali., 13ull. Mns. Comp. Zö̈l., XII, p. 220 (in part), pl. 15, tigs. 4 a, 4b, 188t; 13ull. U. S. Nat. Mus., No. 37, p. 34 (in part). pl. 1 , figs. $4 a, 4 b, 1889$.
Cyclopecten subimbrifer Vermill and Busit, in Verrill, Trans. Conn. Acal., X, pp. 84, 92, 1897.

Shell small, inequivalved, white or grayish white, translucent, length and height nearly equal. Dorsal margin straight. Anterior auricle in the left valve rather large and broad, the onter end obtusely romded,
covered with small, close, radial ribs and crowded concentric ridges; posterior anricle much smaller, with from one to three faint, radial ridges and many concentric, raised lines, and with its outer eud forming less than a right angle, with a slight incurved notch below. In the right valve the anterior auricle has a similar radial sculpture and the byssal notch is rather deep and narrow. The dorsal lines of the body of the shell form rather less than a right angle; the ventral margin forms nearly a semicircle with an obtnse angle where it meets the dorsal outline. Umbos a little prominent; beaks small, acute, smooth, and projecting beyond the margin of the hinge. The surface of the left valve is covered with slightly raised concentric lines, which are interrupted or broken up by small arched scales which are sometimes semicircular, but more frequently somewhat angulated or $V$-shaped, and usually are separated by intervals abont equal to their breadth; these scales vary in number, but are usually arranged in about forty radial rows, and increase regularly in size from the umbos, where they are replaced by thin, slightly raised, radial lines crossing the stronger, more elevated, concentric lines, but not rising into points. In some specimens the radial arrangement is scarcely disceruible; the scales appear as irregularities in the concentric lines. The postero dorsal area below the auricle is nearly smooth, except for the fine lines of growth, but sometimes shows minute granules. The riglit valve. which is smaller than the left, is envered by fine, thin, close, concentric, raised lines, which sometimes show microscopic striations. The anterior auricle is decussated by from six to eight, or more, small radial ridges, which are crossed by the raised, concentric lines; the latter rise into sharp scales at the dorsal margin; the small posterior auricle has finer concentric lines and only two or three faint, radial ridges.

Comparatively few specimens, at three stations, between N. lat. $42^{\circ}$ $45^{\prime} 30^{\prime \prime}$, W. long. $62^{\circ} 43^{\prime}$, and N. lat. $39^{\circ} 53^{\prime} 30^{\prime \prime}$, W. long. $711^{\circ} 13^{\prime} 30^{\prime \prime}$, in 121 to 312 fathoms, $187 \mathrm{~T}-1885$.
C. Kermadecensis (Smith), from north of Kermadee 1slands, in 600 fathoms, is a related species.

## PROPEAMUSIUM THALASSINUM (Dall) Verrill.

(Platr LAXXVII, fig. 6.)

> Amussinm fenestratum Verrill., Trans. C'oma. Acad., V', p. äs2, 1882.

> I'ropeamnsirm thalassinum Yerrill, Trans. Comn. Icall., X, py. xi, !2, pl. xix, figs. $\overline{\mathrm{j}}-7,1897$.

Found at thirteen stations, between N. lat. $40^{\circ} .5^{\prime} 39^{\prime \prime}$, W. long. 700 $23^{\prime} 52^{\prime \prime}$, and N. lat. $35^{\circ} 42^{\prime}$, W. long. $7 t^{\circ} 54^{\prime} 30^{\prime \prime}$, in 43 to 317 fathoms, 1880-1885. South to Barbados, in 22 to 317 fathoms.-Dall.

## Family A ROID F.

BATHYARCA Kobelt.

## Type--Bathyarcu pectunculoides (Scacehi).

Shell oblong, subovate, or rounded, rather thin, usmally finely cancellaterl, with hairy or scaly epidermis, more or less equilateral, fre quentiy slightly inequivalved, with a slight byssal sinus. Byssus very small. Ligamental area lanceolate, longer and narrower behind the beaks, with a sagittate posterior ligament. Hinge-margin nearly straight, nsually narrow and edentulons in the middle, with a series of small, oblique, striated and cremulated teeth on each end, the distal ones becoming larger and more obligue; those of the posterior series usually longer and more oblique, or divergent, than those in the anterior.
The animal of l3. pectunculoides var. gremdis, preserved in alcohol, has the margin of the mantle plain without ocelli, with a well-developed muscular sep,tum, posteriorly; the foot large and thick, geniculate, pointed posteriorly, with a strong byssal groove and a slender, solid, byssal stem; two pairs of rather small, long, lanceolate palpi: the rectum with a free terminal portion; two pairs of rather large gills, with the posterior end of the stem free for some distance, curved, and tapered to a point, and with the reflected portion of the filament of the same length as the direct; the filaments are very slender, delieate, and soft aud but slightly attached to each other.

This division, which is probably of generic value, includes a number of small and mostly deep-water species which have been varionsly placed by recent authors. Mr. E. A. Smith puts several of them in Scaphericu with a mark of donbt. Mr. Dall puts two allied species in the Jurassic genus Mucrodom. ${ }^{1}$ with which they do not seem to agree very closely, and mentions the affinity of others to Barbatio.

The last gromp differs in the stont, rough shell, strongly gaping rentrally for the large byssus, and in the character of the teeth and ligament. Scapharce has a thick, strongly ribbed, inequivalved shell, a firm byssns, and continuons, strong, lanceolate ligament. Macrodon has, on the posterior hinge-plate long, divergent lamellar, nearly parallel with the dorsal margin.

We would refer the following speeies to Bathyarca.-B. pectuncu-

[^12]loides (scarchi) and its varieties, grandis Verrill, Freilei Jefireys, septentriomalis Sars, cromulata Verrill, orliculuta Dall, from off St. Vincent, northwatd. B. ylncialis (Gray), Arctic America and Europe. B. cnomalu Verrill and Bush, (inulf of Maine. B. chyyssorum Verrill and Bush, oft' Delaware Bay. B. profumlicola Verrill, from off" West Indies, northward. B. ylomernla (Dall), B. polycymu (Dall), B. culebrensis (Smith), off West Indies. 13. imequisculptu (Smith), B. pteroessa (Smith), Atlantie and D'acific. B. imituta (Smith), P'acific.
bentharca aspervla (Dall), and 73 . sat!rinatu (Dall), are from the West ludies. in deep water.

## BATHYARCA ABYSSORUM, new species.

( Plate LNXII, fis. 9.
Shell small, short, well-romded at both ends, swollen, inequilateral, slightly oblique. with a rather long, straight hinge-margin. I'mbos large, swollen. prominent. Beaks prominent and curved strongly forward, situated considerably in front of the middle. Surface everywhere covered with nearly equal, delicate, raised, radiating lines and small, rather even, raised lines of growth; these together prodnce a finely canceilated surface which, when fresh, is covered with a thin brownish-yellow epidermis forming small scale-like points at the intersertion of the lines; the surface is also marked with slight, irregular, concentric waves or undulations.

The anterior margin is shorter than the posterior and forms an obtuse, rounded angle at its junction with the hinge-margin; the ventral margin is obliquely curved, most prominent behind the middle, where the curve forms nearly the segment of a circle: posterior margin is very broadly rounded and forms a distinct obtuse angle where it joins the dorsal margin. The ligamental area is lanceolate moderately large, decidedly wider just in front of the beaks, becoming narrow and pointed posteriorly. The dark ligamental patel is arrowshaped, sitnated behind the beaks. The hinge-margin is rather wide and strong, with a small, central elentulous space, mostly behind the beaks. The teeth, which are striated on the sides and eremulated on the edge, are efually and deeidedly oblique in the two series; the proximal ones are small and the others increase in size and obliquity to near the end of the series, where one or two of the outermost are decidedly smaller and very oblique. In the largest specimen there are about six teeth in the anterior and eight in the posterior series. The imer surface shows faint radial grooves and ridges, much coarser than the external strie'; there is also a fine, impressed line, with a finely crenulated edge close to the margin.

Length of the largest speeimen, 6 mm .; height, 6.5 mm .; thickness, 5.5 mm .; length of the hinge margin, 3.5 mm .

Three specimens were found at stations 2713 and 271.4, off Delaware Bay, in 1,825 to 1,859 fathoms, 1886.

This suceries is allied to 73. glomeruld Dall. The latter differs in has ing a less rounded form with a longer hinge-margin, more definite terminal angles, and much more numerons and smaller teeth which are nearly continnous. In our specimens of 13 . ylomerula of corresponding size, there are abont ten teethin each series and they are about one-half as large. According to Mr. Dall's figures, the umbos of his species are larger than in the more northern form, hat our specimens of his species have the umbos smaller than is indicated by his figures. The position of the beaks and form of the ligamental area is nearly the same in both species; but the latter appears to be a little wider in ours and the beaks are a tritte more oblique. The external sculpture is similar but the radial lines are decidedly stronger and less numerous in glomeruln, and the sculpture is quite different in the two valves, while in ours there is no perceptible difference. 13. inuequiseulpta (Smith) is also a closely allied species which Mr. Dall considers identical with B. glomerulu. Mr. Smith's figures are quite different from those of Mr. Dall, and also from our West Indian specimens of the latter, and still more different from 13 . abyssorum.

## BATHYARCA PROFUNDICOLA. (Verrill).

(Flate LXXVIII, fig. り.)
Area profundicola Tehrili, Trans. Comm. Acad., VI, p. 439, pl. xliv, figs. 23, 23a, 1×85.-Dali, Bull. Mus. C'omp. Zoül., XII, y. 245, 1886.
Macrodon profumdicola Dall, Bnll. U.S. Nat. Mus., No.37, 1. 42, pl. xlvi, figs. 23, $23 a, 1889$.
A very few specimens, at three stations, between N. lat. $40^{\circ} 29^{\prime}$, W. long. $666^{\circ} 4^{\prime}$, and N. lat. $37^{\circ}$, W. long. $71^{\circ} 54^{\prime}$, in 1,769 to 2,620 fathoms, 1884 and 1885. Also among Foraminifera, station 2385, N. lat. $28^{\circ} 51^{\prime}$, W. long. $88^{\circ} 1 s^{\prime}$, in 730 fathoms.

## BATHYARCA ANOMALA, new species.

## (PIate LAXVII, fig. R.)

Shell small, oblong, inequilateral, much swollen with large prominent umbos, and pointed beaks, curved strongly forward and considerably separated, owing to the umsually wide, lanceolate, ligamental area, which is covered behind the beaks with the remains of a dark thickened ligament. Dorsal margin straight for nearly its entire length; anterior and posterior ends broadly and about equally rounded, the posterior a little the more swollen below and longer; ventral margin broadly romded, a little prominent in the middle, with a slight byssal indentation in front. Surface everywhere covered with fine, regular, raised, radiating lines which are decussated by finer lines of growth; the rather thin brown epidermis is scaly or chaffy on the radii, especially towarl the margins, where it forms miunte points. Hinge-margin considerably thickened, increasing in streugth toward the ends; in the
middle, where it is narrowest, it is nearly smooth and rounded, with only slight indications of one or two transverse teeth on each side; next these there are two or three somewhat oblique, slightly divergent, irregular, longitudinal, slightly striated and crenulated folds, separated distally by rather deep grooves nearly parallel with the inner margin. The imer edge of the ventral margin is thin and plain.

Length, 8.5 mm.; height, 7 mm .; thickness, 6 mm .
One living specimen (No. it4081) was dredged by the lache at station 52 , oft Cashes Ledge, in 27 fathoms, 1874.

As only a single specimen has been fomd, it is possible that it is but an abnormal variety, althongh it appears to have been healtly and well-grown in every respect. It is related to 13 pectunculoides (Ilate LXXIII, fig. 6), but differs remarkably in the character of the hinge, which has the transverse teeth scarcely discernible, and obligne, irregular folds on the distal parts of the margin, and also in the greater width of the ligamental area.

## Family LIMOPSID.E.

## LIMOPSIS SULCATA, new species.

(Plates XCII, fig. 2; XCV, fig. ! : XC'I, fis. 1.)
Shell rery oblique (yomg specimens are less oblique and in some cases are more nearly circular), broad ovate, the posterior ventral margin much produced and obtusely rounded: aurieles only slightly devel. oped. The dorsal margin is short and straight. with a marrow, smooth area beneath the beaks; the anterior margin is subtruncate, or very obtusely rounded; the ventral margin is oblique, broadly romuded. forming an obtusely rounded angle with the posterior margin, which is strongly sloping and only a little convex. The umbos are small and somewhat prominent; the beaks small. pointed, and curved inward. The entire surface is covered with strongly marked, concentric grooves and prominent ronded, narrow ribs; the latter are crossed by mumerons fine, radiating, incised striations, which divide them into beadlike, or squarish, portions, which are most obvions on the middle and posterior parts and become very faint anteriorly. The hinge-margin is much thickened and bears a curved series of rather large, flattened teeth, of which about eight are situated in front of the beaks and about ten behind them; those nearest the center are small; the resilial pit extends upward to the beak in the form of a small triangular denession. The inner surface of the shell is marked by fine, radiating striar; the margin is thickened and cut away near the edge; no cremulations have been observed in our specimens.

Greatest length, 12 mm .; greatest height, $1 \% \mathrm{~mm} .:$ breadth, 6 mm .
A number of separate valves, at about ten stations, between N. lat. $40^{\circ} 8^{\prime}$, W. long. $68^{\circ} 45^{\prime}$, and N. lat. $377^{\circ} 7^{\prime} 4^{\prime \prime}$, W. long. $74^{\circ} 35^{\prime} 40^{\prime \prime}$, in 64 to 349 fathoms, $1580-1854$.

## LIMOPSIS MINUTA (Philippi).

## (Plates LXXV, fig. I; LXXVHI, fig. 7.)

Limopsis minutu Verrild Trans. Conn. Acarl., V, 1. 576, 18×2; VI, p. 280, 1881 ; Expl. Albutross, Report U.S. Com. Fish and Fisheries for 1883, 1. 577, 188...-Snitı, E. A., Report Voy. Chullonger, Zoöl. Lamellibranchiata, XlII, p. 20.s, 1885.-Da1L, linll. Мus. Comp. Zoöl., XII, p. 236, 1886; Bnll. IT. S. Na1. Mıs., No. 37, p. 12, 1889.-Busir, Bull. Mus. Comp. Zoöl., XXIII, p. 235, pl. ı, lig. 8, 1893. -Lucard, Campagne du Caulan, Annales de l'Université de Lyon, p. 198, $18: 16$.

A very common and abundant species, at eighty-two stations, between N. lat. $44^{\circ} 7^{\prime} 30^{\prime \prime}$, W. long. $57^{\circ} 16^{\prime} 45^{\prime \prime}$, and N. lat. $35^{\circ} 49^{\prime} 30^{\prime \prime}$, W. long. $74034^{\prime} 45^{\prime \prime}$, in 116 to 2,221 fathoms, 1880-1887. Sonth to Barbados, in 30 to 2,221 fathoms.-Dall.

## LIMOPSIS AFFINIS Verrill.

## (Plate LXXY, fig. 2.)

Limopsis affinis Verlille, Trans. Conn. Acad., VI, 1. 4!2, 18s5.
Two live specimens, at station 2092 , N. lat. $39^{\circ} 55^{\prime \prime} 35^{\prime \prime}$, W. long. $71^{\circ}$ $30^{\prime \prime}$, in 197 fathoms. 185:3.

## LIMOPSIS PLANA Verrill.

(Plate LXXV, fig. 5.)
Limopsis sp. (?) Verrill, Trans. Conn. Acarl., V, p. 280, 1884.
Limopsis plana Verrile, Trans. (!omn. Acad., VI, p. 4.11, 1882; Expl. Albaboss, Report U.s. Com. Fish and l'isheries for 1883, p. 577, 1885.

Limopsis planu Busir, Bull. Mıs. Comp. Zoöl., XXIII, pp. ㄹ40, 24, pl. н, tigs. 19, 20, 1893.

Three live specimens and one valve, at two stations, between N. lat. $38^{\circ} 22^{\prime}$, W. long. $70 \supset 17^{\prime} 30^{\prime \prime}$, and N. lat. $3^{\circ} \supset 40^{\prime} 30^{\prime \prime}$. W. long. $70 \circ 37^{\prime} 30^{\prime \prime}$, in 1,82.5 to 2,221 fathoms, 1883-1886. South to Dominica, West Indies, in 1,131 to 2.221 fathoms.-Dall.

The largest specimen, from station 2710 , is 18.5 mm . long; 18.5 mm . high; linge-margin, 11 mm . long; ligamental area, 3 mm . long.

## LIMOPSIS AURITA (Brocchi) Jeffreys.

(I'late INXV, fig. B.)
? Aren aurita Bisocen, Conch. foss. Subap., II, p. 485, pl. xi, fig. 9 (t. Jeffreys).
 fig. I, IsG9.--Smitn, E. A., Report Voy. Challenger, Zoül., Lamellibranchiati,, XlII, p. 257, 1885.-Dall, Bull. Mus. Comp. Zö̈l., XII, p. 237, 1886; 13ull. L'. S. Nat. Mus., No. 37, p. 12, 1889.-Locari, Campagne du Camlan, Annales de l'Université de Lyon, p. 197, 1896.
Not Limopsis aurita, variety, Verrile, Trans. ('onn. Aead., V'I, p. 440, 1885.
One valve, among Foraminifera, station 2385 , N. lat. $28^{\circ} 51^{\prime}, ~ W . ~ l o n g . ~$ sis $18^{\prime}$, in $7: 00$ fithoms. sonth to (iremada, in 21 to 1,582 fathoms.Dall.

The northern specimens ( $L$. profundicola) formerly referred donbtfully to this species prove to be distinct. The single specimen now inchuled agrees well with a specimen of the fossil form from Europe.

## LIMOPSIS PROFUNDICOLA, new species.

(I'lates LXXV', fig. \& ; LXXXII, fig. 4.)
Limopsis antitu, variaty (!) Vermill, Trans. Conn. Acad., VI, P. I10, 1885.
Compuratively few specimens, at ten stations, between N. lat. $41 \circ \mathrm{~T}^{\prime}$, W. long. 6: $\mathrm{O}^{\circ} 26^{\prime} 30^{\prime \prime}$, and N. lat. $36^{\supset} 47^{\prime}$, W. long. $73 \circ 9^{\prime} 30^{\prime \prime}$, in $1,5 \pm 5$ to 1,859 fathoms, $1884-1586$.

## Family MYTLLID.E.

## CRENELLA FRAGILIS Verrill.

(1'late LAXXIII, ligs. 1, 2.)
 Nat. Mus., No. 37, p. 10, 1889.
One valve and a fragment, station 22650 , N. lat. $3 \mathrm{~B}_{1} 7^{\prime} 40^{\prime \prime}$, W. long. $74^{\circ} 35^{\prime} 40^{\prime \prime}$, in 70 fathoms, 1884.

> GLOMHD.E, new family.
(ilomime Verrill and Busir, Amer. Jonm. Sici., III, 1P1. 53, 59, Jamary, 1897.
Shell short, romblish at both ends. Hinge-plate with a row of transverse teeth each side of the middle. Ligament thick, elongated, attached for most of its length to the inner surface of the posterior hinge-plate and ruming forward in a narrow groove beneath the beaks, so that its anterior portion is external and its thickened posterior portion is partly internal. No pallial simus. Animal not known.

This group includes, so far as known, only the genus Glomus . Teffreys, which has been referred by several writers to the Arcidar, and by others to the Ledide, from both of which it differs widely. Its relations to the Nucnlidar are somewhat uncertain, owing to our ignorance of the soft parts. In the form and position of the ligment it differs entirely from all other genera of Nuculida and Ledidae.

A more mature consideration of this group. since the publication of our former article, leads us to consider it as a family distinct from Nuculidie.

## GLOMUS Jeffreys.

(Alomus Jeffiey', Annals Mag. Nat. Hist., p. 433, November, Isio.-Veriblel and Be'sir, Amer. Jouru. Sei., III, pp. 53, 59, January, 1897.

Type-Glomus nitens Jeflireys.
Shell thin, smooth, smbequilateral, romuled at both ends, with the beaks turned forward. No lumule or esentcheon. Hinge with two series of obliquely transverse teeth; a small lateral tooth may be present.

The following are described species:
(i. nitens Jeffreys, North Atlantic (Europe) and from off Marthas Vineyard south to off Rio de la llata (America); G. jeftreysi Smith; (i. simplex Smith, and G. incequilateralis Smith, West Indies; (i. juponious Smith, off Japan.

## GLOMUS NITENS Jeffreys.

## (Plato XCVII, ligs. 1,2.)

(ilomus nitens Jeffreys, Amals Mag. Nat. Hist., p. 433, Novemher, 1876; Proc. Zö̈l. Noe., London, p. 573, pl. xly, fig.5, June, 1879.-Verrill, Trans. Comn. A'aul.. VI, p. 231,1884 ; Expl. Albatross, Report IT. S. Com. Fish and Fisheri's for 1883, p. 576, 1885.-Smiti, E. A., Report Voy. Challenger, Zoil., Lamellibranchiata, XIII, p. 248, 1885.-DAll, 13ull. U. S. Nat. Mhs., No. 37, 1. 46, 1889.Verridl and Busir, Amer. Journ. Sci., III, p. 53, figs. 1, 2, Janary, 1897.

The suecimens which we refer to this species agree closely in size and form with Jeffreys's figures, but there is in both valves a small submarginal lateral tooth fust beyond the posterior series of teeth, and in the right valve a similar but less prominent one just beyond the anterior series. These are not mentioned in Jeffreys's description. In the posterior series there are fewer teeth than in his figure and they have an acute, oblique, $V$ shaped outline and are but little raised; in the anterior series there are four larger, oblique teeth which are not so distinetly $V$-shaped, owing to their oblique position and becanse the surfare of the hinge-plate is turned downward. The posterior ligament is strong, long, wedge-shaped, widest distally where it occupies most of the wirlth of the hinge plate; the narrow prolongation rums forward muder the beaks in a narrow groove. There is a thickened, edentulous space under the beaks, separating the two series of teeth, which has, when highly magnitied, a very small, angular notch in the middle of its lower edge, which in our specimen is filled with what appears like the remans of a resilium; there is also a very minute, $V$-shaped noteh in the external margin. The beaks turn forward. The pallial impression is rather indistinct, but appears entire. Interior somewhat lustrous, but mot at all macreous.

Two imperfect specimeus, at two stations, off Marthas Vineyard and off Delaware Bay, in 1,544 and 1,608 fathoms, 1883 and 1886. South to Rio de la Plata, in 294 to 1,900 fathoms.-Dall and Smith.

REVIFW OF THE GENERA OF LEDIDA AND NUCULIDA OF THE ATLANTIC COAST OF THE UNITED STATES.

These families are often united by modern malacologists under a single family (Nuculidae), while others regard them as distinct. They are certainly closely related anatomically, as well as by the structure of the shell. Thins all the members of both families have a single pair of

[^13]simple "foliobranchiate" (or protobranchiate) gills; two pairs of large labial palpi, the outer ones furnished with long extensile labial tentacles; a large muscular foot with an expanded, concave, terminal disk, adapted for rapid motions in jumping and swimming, as well as for creeping; and all have two series of transverse or oblifue teeth on the hinge-margin. The peculiar structures of foot and gills appear together elsewhere only in the family Solemyidx. which is evidently a related group, though it lacks hinge-teeth and has a very different shell. As these three families hare gills of a peculiar and simple structure, each one consisting of two rows of flat lamelle, attacherl to a single stem, they have recently been regarded as forming a special order (Protobranchiata).

This group is of special interest becanse of its great antiquity. Large numbers of fossil forms very closely allied to existing genera and species oceur even in Silurian and Devonian formations.

Thus the common living genera Trucula and Ledu are represented by numerous Devonian species, many of which tan not be separated from the recent forms, even as subgenera, by any tangible characters. Other species of the same age, referred to Paluoneilo, agree in nearly all essential eharacters with the living genus Tindaria. These fossil shells are generally larger and stronger than the corresponding living species. Many Paleozoic genera which are now extinet were as highly organized and as mnelı specialized as their living allies.

The thin-shelled, strongly siphonate genera, such as Yoldia, Toldiella, ete., do not appear so early in geological time and may be regarded as more modern specializations of the leda-like forms. They are also the forms that swim and jump with the greatest activity. Therefore the thin and light eharacter of their shells may be regarded as laving been secondarily acquired, partly in consequence of their active movements, in which a heary shell would be disadrantageous, and partly beeause the development of long siphous enables them to live concealed much of the time beneath the surface of the soft mud in whiel they generally live. In Solemya the shell is still lighter and thinner, in accordance with more developed swimming habits, combined with burrowing when at rest. Such forms as Iruculn and Tinduria, which have no siphon tubes, must live at or near the surface of the mud, over which they creep with their large expanded pedal disk. These have, for their protection, comparatively solid shells similar to those of Palieozoic spe(cies, in form, texture, and sculpture.

The family Nueulide differs from Ledida mainly in having no siphon tubes, the mantle edges beiug completely disunited. The Ledidar are remarkable for the great variations in the structure of the hinge-teeth, ligament, cartilage, and mantle, as well as in the form of the shell. The pallial simus may be wanting or well developed. Some genera have long united siphons (Yoldia); some have shorter ones, more or less separated (Ledu); while in Timduriu there is no true siphon, but only an Proc. N. M. vol. xx-jt
efferent orifice differentiated. The ligament may be wholly external, as in Malletic, Tindaria, ete., or it may be rudimentary and replaced ly an internal cartilage or "resilium," or both may coexist in varying degrees of development and degeneration. The hinge-teeth may be very numerous and regularly V-shapel in each series, or they may be comparatively few and irregular, sometimes becoming oblique and lamelliform (Siliculta). The beaks generally turn backward (Yoldia, Ledn, Nucula), bat in Malletia, Tinduria, and some other genera they turn forward. On this account, when there is neither pallial sinus nor external ligament, it is often difficult, if not impossible, to tell which is the anterior end of the shell without the soft parts. Hence many fossil and some recent species have probably been reversed in the descriptions. Thus many of the Palrozoic species referred to Nucula are described as having the beaks turned forward, the longer end of the shell being considered posterior, but in modern Nucule the beaks turn backward and the shorter end is posterior. Many of the deep-sea species with small, thin shells show no distinct muscular nor pallial scars, which increases this difficulty. When a differentiated exterual ligament is present, we have assumed that it is posterior to the beaks (opisthodetic), thongh a narrow exteusiou usually rums under and forward of the beaks in a groove. When the shell of a dimyarian bivalve gapes posteriorly, the existence of a siphon may generally be assumed; for otherwise the internal soft parts would be exposed to enemies. The existence of a posterior rostrum or a protrusion of the posterior margin defined by an inferior emargination indicates the existence of a siphon, or at least an anal tube, but these organs may exist without such modifications of the shell. If these rules be applied to Palrozoic forms we must conclude that the rostrate and subrostrate forms of Palconeilo, etc., had some sort of a siphon, and therefore were not true Nucnlide.

Numerous Palaozoic species referred to the genus Palconeilo probably belong to or near the Tindarina. Some of the species ${ }^{1}$ from the American Devonian rocks can hardly be distinguished from Tindaria by any important structural characters, unless it be the form of the teeth. It is probable that Nuculites and several related genera beloug near this division, for they have an external ligament and no resilium. In these genera the plain, transverse teeth are very numerous and more simple than in the modern genera, seldom showing any trace of the acute, V -shaped form characteristic of most modern genera, though in some species the teeth are slightly angulated in the middle.

Mr. Dall has proposed the family Ctenodontidar ${ }^{2}$ to include numerons Palaozoic species belonging to Ctenodonta, and allied genera, some of which Zittel and others refer to Arcide on account of their thickened pectunculoid shells. They seem to be allied rather to Tindarina.

[^14]The Ledide, as here understood, were divided into five subfamilies by Fischer, namely:
(1) Cucullelline $=$ Ctenodontidæ Dall + Palconeilo and Cardiolaria; (2) Sareptin:e (for Sarepta only); (3) Ledinæ; (4) Malletine (including Tindaria); (5) Lyrodesmatina (for ancient fossil forms like Lyrodesma, but including the living genus Phaseolus or Silicula). An additional group was formed for some other doubtful fossil genera. The second of these groups is not well founded, for Sarepta agrees closely with Yoldia, except in the alleged absence of a pallial sinus, but its gaping shell indicates a siphon tube. The fourth should not include Tindaria, which lacks the pallial sinus and siphon tubes characteristic of the rest of the group aud should be taken as the type of a new subfamily. The fifth shonld not include Phaseolus, which differs widely from the fossil forms and belongs in the Ledina. The other genera of this group are referred to Trigoniade by other anthors, and that would seem to be a more correct arrangement.

## Family NUCULIDE.

## NUCULINA d'Orbigny, 1845.

Pleurodon S. Wood, 1840.
Nuculina d'Orbigny, 1845.
Nucinella S. Wood, 1818.
Nuculina Verrill and Bush, Amer. Journ. Sci., III, pp. 53, 59 , January, 1897.
We have included Nuculina in the Nuculide with some doubt, because authors differ as to its structure. Some state that its ligament is wholly external and others to the contrary. Fischer places it in the Arcidre, near Limopsis, but it has no ligamental area.

Mr.Dall kindly forwarded to us excellent unpublished figures of two American species of this genus. In these the thickened ligament is external to the hinge-plate, on the end of the shell which is destitute of a lateral tooth, and is the shorter (posterior?). The beaks turn toward this end. Mr. Dall states that the shells are not distinctly nacreous within.

The following are some of the known species:
N. miliaris Deshayes; N. ovalis S. Wood; N. calabra Seguenza, fossil; N. munite Carpenter, from the Catalin Islands; N. sulcata A. Adams, from Korean Straits; N. adamsi Dall, from Florida and the West Indies.

## NUCULA Lamarck, 1799.

Nucula Lamarck, Prodrome d'une Nouv. el. des Coqnilles, p. 87, No. 104, 1799.
Nuculana Link, Beschr. Rost. Samml., p. 155, 1807 (not of Adams, 1858, nor of Harris, 1897).
Nucula Dall, Bull. Mus. Comp. Zoöl., XII, p. 245, 1886.
Type.-Nucule nucleus Lamarek.
Nuculana (Link) was an exact synonym or variant of Nucula, of earlier date, as the description plainly shows. There was, therefore,
no valid exense for applying it to a different group (Leda), that had already received a valid name, as was done by II. and A. Adams.

That a species belonging to Leda was mentioned by Link does not alter the case, for all the species of Ledu and Yoldia then known were referred to Nucula by Lamarek and all other conchologists.

NUCULA PROXIMA Say, variety OVATA, new.
(Plates LAXXI, fig. f; LXXXVIII, fig. 5.)
We designate by this name a single specimen which differs so widely in form from the ordinary type of Nucula proxima that it could well be takenfor a distinct species if it had occurred in large numbers or in a remote lorality. It is broad ovate or elliptical in form and much less angular and oblique than the typical proxima. It is decidedly compressed with the umbos much less prominent than usual. The smface is glossy, grayish white, marked with distinct lines of growth and microscopic radiating strie. The anterior end is evenly romded and more produced than in proxima: the ventral margin is broadly and evenly rounded; the posterior end is obtuse, slightly produced and scarcely angulated; the postero dorsal margin is convex and slopes much less rapidly than in proxima, so that the posterior end is more evenly rounded and broader. Internally the margin is plain. The hinge-teeth are much as in proxima. but the two series are less curved and meet in a broad angle.
Length, 3.5 mm .; height, 3 mm .
One live specimen (No. 73467), station 863, in Vineyard Sonnd, off Cuttyhunk, in 1s fathoms, 1580 .

## NUCULA SUBOVATA, new species.

(Plates LAXXI, fig. 8; LXXXIL, fig. 5.)
Shell small, broad ovate, with somewhat prominent umbos, and rather acute, somewhat prominent beaks behind the middle. Surface smooth and lustrons, covered with rather regular, concentric lines of growth, which are scarcely visible to the naked eye. Epidermis thin, pale yellowish green. The anterodorsal margin is nearly straight at first; then, forming a convex curve, slopes gradnally to the bluntly rounded anterior end which is somewhat prodnced but not angulated; the postero dorsal margin is convex, sloping rapidly, and forms a slight rounded angulation in the middle of the posterior end, where it joins the broadly romded, ventral margin. Hinge-margin rather broad and strong in proportion to the size of the shell, with a moderately large ronnded, slightly oblique ehondrophore projecting considerably within the margin. The portion of the hinge-plate behind the beaks is considerably shorter than that in front and bears about six, strong, $V$-shaped teeth of which the two distal ones and the two proximat ones are much smaller than the others; in front of the beaks it is broad and
strongly curved，and bears about nine broad，elevated．strong，trans－ verse teeth of which five or six in the middle are much larger than the others；above these the onter hinge margin is somemhat expanded and everted．There is a thin，contimnons ligament both before and behind the beaks．Epidermis thin，pale greenish yellow．The inner ventral margin is thin and plain．

Length， 4.9 mm ．；height， 3.9 mm ．
Some of the smaller specimens have à narrower and less thirkened hinge－plate with the teeth more delieate than in the type．

Four specimens，at four stations，between N．lat．400，W．long． 710 $14^{\prime} 30^{\prime \prime}$ ，and N．lat． $37^{\circ} 8^{\prime}$ ， $\mathbb{I V}^{\prime}$ ．long． $74^{\circ} 33^{\prime}$ ，in 157 to 44 fathoms． 1881－1885．

This speeies has some resemblance to $N$ ．tenuis，but it is much less oblique and more elongated in form，and is less ineuuilateral，the pos． terior end not being subtruncated，while the anterior end is narrower， relatively shorter，and much less oblique．The hinge－margin is also different；the teeth are fewer and much stronger，and the hinge margin much broader，while the chondrophore is smaller，more rounded，much less oblique，and projects freely from the inner hinge－margin instead of being united closely to it．

It also bears some resemblance in form to Nucula pernambucensis Smith，${ }^{1}$ but there are marked difterences in the linge and number of teeth．

## NUCULA GRANULOSA Verrill．

（Plates LANXI．fig．2：LAXXYIII，fig．8．）
Nucula granulosa Verrill，Trams．Comi．Acad．，V1，p．280．1～84：Expl．Albatross， Report U．S．Com．Fish and Fisheries for 1883，p． $576,1885 .-1$ Dald，Bull．U．S． Nat．Mus．，No．37，p．42， 1859.
Taken at about sixteen stations，between N゙．lat． $41-33^{\prime}$ ，W．long． 650 $35^{\prime}$ ，and N．lat． $38^{\circ} 36^{\prime} 3^{\prime \prime}$ ，W．long． $73^{\circ} 6^{\prime}$ ，in 384 to 1,061 fathoms， 1850－1886．

## NUCULA VERRILLII Dall．

（Plate XCT ，fig．10．）
Nucula trigona Verrill，Trans．Comn．Acad．．VI，p．438， 1885 （nut Bronn，1849，not Seguenza，1877）．
Nucula rervillii Dall，Bull．Mus．（＇ompl．Zö̈l，NiI，p．248，1886；Bull．U．S．Nat． Mus．，No．37，p．42，1889；Proc．U＇．S．N＇at．Mus．，NII，p．257，pl．xrr，fig．4，18＊9．－ Bush，Bull．Mns．Comp．Zoül．，XXIII，pp．240，っ243，pl．ı，fig．6． 1893.
Comparatively few specimens．at six stations，between N．lat．39つ $43^{\prime}$ $45^{\prime \prime}$ ，W．long． $70 \supset 7^{\prime}$ ，and N．lat． $31 ; 4^{\prime}$ ，W．long． $73 \circ 9^{\prime} 30^{\prime \prime}$ ，in 1,140 to 1，825 fathoms，1884－1886．South to Yueatan，in 430 to 1，685 fathoms．－ Dall．

[^15]
# NUCULA CANCELLATA Jeffreys. <br> (Plates LXXXI, fig. 3; LXXXVI, fig. 5.) <br> Nucula cancellata Verrile, Trans. Conn. Acad., VI, pp. 231, 280, 1884; Expl. Albatross, Report U. S. Com. Fish aud Fisheries for 1883, p. 576, 1885.-Dall, Bull. U. S. Nat. Mus., No. 37, p. 42, 1889; Proc. U. S. Nat. Mus., XII, p. 258, 1889. 

A very abundant species, at forty-four stations, between N. lat. $42^{\circ}$ $47^{\prime}$, W. long. $61^{\circ} 4^{\prime}$, and N. lat. $37^{\circ} 27^{\prime}$, W. long. $73^{\circ} 33^{\prime}$, in 384 to 2,033 fathoms, 1883-1887. South to off Tobago, West Indies, in 880 fathoms.Dall.

Family LEDIDA. ${ }^{1}$

Subfamily LIFDINAE.

LEDA Schumacher, 1817.
Leda Verrill and Bush, Amer. Journ. Sci., III, pp. 54, 62, Jauuary, 1897.
Nuculana Harris, Cat. British Museum, p. 348, 1897 (not Link, 1807).
Type.-Leda rostrata (Montagu, 1808).
This geuns has been variously extended and restricted by authors, and several subgeneric and sectional groups have been proposed. In the more extended sense it is scarcely capable of a definition that will distinguish it from Yoldia, etc.

We proposed, therefore, to restrict it to the typical species, such as L. cuspidata Gonld, L. caudata (Donovan), L. pernula (Miiller), L. tenuisulcata (Conthouy), and many others closely related. These have a long, tapered, bicarinate rostrum, and well-developed siphon tubes, partially united. The palpal tentacles are long, flat, tapered, and arise external to the bases of the outer palpi, which are broad with slender, acute, posterior tips.

Mr. Harris quotes rostrata Linnæus as the type of his Nuculana, but no such species occurs until Gmelin's edition, 1790 ; rostrata Chemnitz, 1784 , used by Schumacher as the type of Ledlu, is now considered the same as fluviatilis Sowerby and also Schroter, 1779 ; rostrata Lamarck, 1819, is the same as pernula Miiller, 1774 or 6 ?, so that in using rostrata Montagu, 1808, we avoid confusion of names without leading to any misunderstanding of the form of the shell, for all of the above species lave the same rostrated form.

## LEDA BUSHIANA Verrill.

## (Plates LXXIX, fig. 8; LXXXII, fig. 9.)

Leda bushiana Verrill, Trans. Conn. Acai., VI, pp. 229, 280, 1884; Expl. Albatross, Report U.S. Com. Fish and Fisheries for 1883, p. 576, 1885.-Dall, Bull. U. S. Nat. Mus., No. 37, 1). 44, 1889.

A few specimens, off Cape Hatteras, North Carolina, in 516 fathoms, 1883. South to Florida Straits, in 120 to 516 fathoms.-Dall.

[^16]LEDA PERNULA (Müller).
(Plate LXNXII, fig. 2.)
Leda pernula G. O. Sars, Mollusea Reg. Arctica Norregise, p. 35, pl. 5, figs. 1 a-d, 1878.-Jeftreys, Proc. Zoül. Soc., London, p. 574, June, 1879.-Yerrill, Proc. U. S. Nat. Mus., III, p. 401, 1881; Trans. Coun. Acal., V, p. 572, 1882; not VI, p. 280, pl. xxx, figs. 14, 14a, 1884.-Not Dall, Bull. U. S. Nat. Mus., No. 37, pl. xlv', figs. 14, 14a, 1889.
Found at a number of stations between N. lat. $46{ }^{\circ} 23^{\prime}$, W'. long. $52^{\circ} 45^{\prime}$, and N. lat. $37^{\circ} \mathrm{S}^{\prime}$, W. loug. $74^{\circ} 33^{\prime}$, in 25 to 471 fathoms, 1872-1885.

## LEDA CAUDATA (Donovan).

## (Plate LXXXII, fig. 1.)

Arca caudata Donovan, British Shells, pl. Lxxvili ; Chenu ed., p. 50, pl. גvif, figs. 8-12.
Leda caudata Loven, Ind. Moll. Scand., p. 34.-Gouli, Rep. on Invert. of Mass., lBinney's ed., p. 165, fig. 471, 1870.-Tryon, Amer. Mar. Conch., p. 182, pl. xxxvill, figs. 494, 495, 1873.
Leda pernula Verrill, Traus. Conn. Acad., Y, p. 572, 1882, in part; VI, p. 280, pl. xxx, figs. 14, 14a, 1884.—Dall, Bull. U. S. Nat. Mus., No. 57, pl. xly, figs. 14, 14u, 1889.-(?) Bush, Bull. Mus. Comp. Zö̈l., XXIII, p. 234, 1893.
Leda caudata Verrill and Bush, Amer. Journ. Sci., III, p. 54, fig. 19, January, 1897.

This deeper-water form, previously ideutified as Ledla pernula, was found at a very few stations between N. lat. $42^{\circ} 57^{\prime}$, W. long. $69^{\circ} 50^{\prime}$, and N. lat. $37{ }^{\circ} 16^{\prime} 30^{\prime \prime}$, W. long. $74^{\circ} 20^{\prime} 36^{\prime \prime}$, in 102 to 641 fathoms, $1874-1885$.

## LEDELLA Verrill and Bush, 1897.

Junonia Seguenza, Nuculidi terziarie merid. d' Ital., R. Acad. Lincei, p. 1175, 1877 (not of Hübner).
Ledella Verrill and Bush, Amer. Journ. Sci., III, pp. 54, 62, January, 1897.
Type.-Ledella messanensis (Seguenza).
This group includes a large number of small species, both living and fossil, in which the shell is rather short, usually ovate or swollen, with a small, acute or subacute unicariate rostrum, sitnaterl merlially or submedially, and defined below by an emargination or undulation in the postero-ventral margin. The postero-dorsal margin is convex. The escutcheon or ligamental area is very distinctly defined by the carina, but is not sunken. The chondrophore is usually small but distinct. The siphon tubes are separate, at least in some species. It includes numerons minute tertiary species referred by Seguenza to the section of Ledre named by him Junonia, and also a considerable number of recent deepwater species generally described by anthors under Ledu. As the name Junonia was preoccupied, the group, which seemed to be of generic value, required a new name.

The following species appear to belong here:
L. seminula (Seguenza), L. micotre (Seguenza), L. peraffinis (Se-
gnenza), L. rectidorsutu (Segnenza), L. confusa (Segnenza), fossil; L. solidula (Smith) and L. semen (Smith), from off Brazil; L. confinis (Smith), off the Azores; $L$. inopinata (Smith), L. prolata (Smith), and L. ultima (Smith), from the Pacific; L. messanensis (Seguenza), from off the Barbados, northwart: L. messanensis (Seguenza) var. subleris Verrill and Bush, off Delaware Bay, northward; and L. parva Verrill and Bush, off Marthas Vineyard.

## LEDELLA MESSANENSIS (Seguenza).

## (Plate LAXXI, fig. 9.)

Leda acuminata Jefrreys, Ami. Mag. Nat. Ilist., p. 69, Jnly, 1870 (not Von Bucif).-seguenza, Nuculidi terziaric merid. d' Ital., R. Acad. Lincei, 1877, p. 1175 , pl. 111, figs. 15, $15 a, 15 e$.

Lela messanemsis Jeefreys, Proc. Zö̈l. Soc. London, p.576, June, 1879.—Smithe, E. A., Report Voy. Challenger, Zö̈l. Lamellibranchiata, XIII, p. 237, 1885.Dall, Bull. Mus. Comp. Zoül., XII, p. 249, 1886; Bull. U. S. Nat. Mus., No. 37, p. 44, 1889.
The shell which is here regarded as the true messanensis is small, swollen, ovate, nearly equilateral, with a distinct, short, oblique rostrum bent downward at the tip and separated from the body of the shell by a distinct depression and marginal indentation. The shell is thick and solid for so small a species; its surface is covered with fine, regular, raised, thin, concentric lines separated by wider concave grooves. The hinge-margin is thick, strong, with about seven or eight, mostly strong, nearly erect, and not crowded, teeth in each series. The chondrophore is relatively large, triangular, and projects on the inner margin. The epidermis is pale yellow. According to Jeffreys the siphon tubes are long and separate.

Length, about 2.6 mm .; height, about 2 mm .
A few specimens, at three stations between N. lat. $38^{\circ} 29^{\prime}$, W. long. $73^{\circ} 9^{\prime}$, and N. lat. $37^{\circ}$, W. long. $71^{\circ} 54^{\prime}$, in 965 to 2,620 fathoms, 1884-85. South to the Barbados, in 32 to 2,033 fathoms.-Dall.

LEDELLA MESSANENSIS (Seguenza) variety SUBLEVIS, new.
(Plate LNXXI, fig. 7.)
Foldia messanensis, variety Verrill, Trans. Conn. Acad., VI, pp. 227, 280, 1884 ;
Expl. Aibatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885.
Letella messanensis, variety Verrill and Bush, Amer. Jonrn. Sci., III, p. 60,
fig. 13, January, 1897.
This variety differs from the form above deseribed, primeipally in having the concentric sculpture wholly or partially obsolete and in its somewhat more clongated form. It has nine or ten teeth in each series, due perhaps to the larger size of the specimen.

Comparatively few specimens, at thirteen stations, between N. lat. $42^{\circ} 47^{\prime}$, W. long, $61^{\circ} 4^{\prime}$, and N. lat. $38^{\circ} 20^{\prime}$, W. long. $70^{\circ} 8^{\prime} 30^{\prime \prime}$, in 1,188 to ${ }^{2} 033$ fathoms, $1883-1886$.

Ledrlla parra Veminl amd Busin, Amer. Journ. Sci., IIT, p. 5i, fig. 18, Jammary, 1897.

Shell minnte, narrow-ovate, the anterior end the longer and obtusely rounded, and the posterior end with a short, subtruncate, median rostrum. Umbos somewhat swollen; beaks a little prominent and turned slightly backward. The surface is nearly smooth, showing only microscopie lines of growth. The antero-dorsal margin is elongated, slightly convex, and slopes very gradually to the romded anterior end; the ventral margin is broadly and evenly convex, but somewhat pinched up posteriorly to form a slight emargination below the rostrum, which is short, narrow, subtruncate at the tip, and is defined by a slight, inconspicuons ridge; the postero-dorsal margin is nearly straight and slopes rapidly to the upper angle of the rostrum. The hinge-plate is strong, considerably thickened, with a very obtuse angle at the beak; the anterior portion is the longer with the inner margin convex, and the posterior portion is the wider, more oblique, with the inner margin strongly concave; the plain onter margin is sharp and projects considerably above the teeth which are strong, stand nearly ereet, and are less V-shaped than usual. There are about fifteen in the anterior series, of which three or four proximal ones are quite small, and nine stonter ones in the posterior series, including one very small one next the beak. The chondrophore is rather small and deep with a distinctly projecting inner edge.
length, 3 mm .; height, 2 mm .
One valve (No. 78365), station 2689, off Marthas Vineyard, in 525 fathoms, 1886.

This species seems to be closely allied to $L$. semen (Smith) from off the coast of Brazil (Voyage of the Challenyer), but that species, although of the same size, has fewer teeth, nine of which are said be anterior and twelve posterior.

## PORTLANDIA Mörch, 1857.

Portlandia Yerrill and Busif, Amer. Journ. Sci., III, pp. it, 62, January, $1 \times 97$.
Type.-Portlandia aretica(Gray) $1819=$ Lerda portlandiea (Hitchcock).
We consider this a distinct genus, but would restrict it to the original type, muless a few species, which we have not seen, should prove to lelong to it. In any case it does not appear that any of the northern species of Europe and America that have been referred to it are really closely allied to the type. In many respects this genus is intermediate between Leda ancl Yolria. In its closed shell, definite rostrum, etc., it agrees more nearly with the former, but in general outline, with the latter.

## YOLDIA Möller, 1842.

Yoldia Verrill and Bush, Amer. Journ. Sci., III, pp. 55, 62, figs. 12, 16, January, 1897.

Type.-Ioldia hyperborea Torrell = Yoldia aretica Mïller (not Gray).
We lave restricted this genus to the typical forms, such as Y. limatula (Say), I. sapotilla (Gonld), Y. myalis (Conthouy), and many closely allied foreign species.

These have a nearly smooth, compressed, lanceolate, gaping shell, more or less prolonged and tapered posteriorly, with a poorly defined, wide rostrum, generally without carinations. The external ligament is marginal, feebly developed, contimous under the beaks, and not much differentiated from the general epidermis. The chondrophore is large, concave, and projects within the margin. The pallial sims is large and deep. The siphon tubes and posterior pallial tentacle are long. The palpal tentacles are long and tapered; in life they may extend nearly to the end of the expanded siphon.

## ADRANELLA, new subgenus of Yoldia.

## Type.-Adranella casta, new species.

This subgenns is allied to Yoldia, but is distinguished by its oblongovate, compressed form, with a broadly rounded, posterior end, having a very small, nearly obsolete, rostrum. Surface senlptured with distinet, raised, concentric lines. Hinge-plate and teeth strong. Resilium occupying a distinct pit in the apex of a large shelf-like, triangular chondrophore.

## YOLDIA (ADRANELLA) CASTA, new species.

## (Plate LXXX, fig. 4.)

Shell small, oblong-ovate, somewhat compressed, inequilateral, with the posterior end a little the longer and cousiderably the broader. Umbos small; beaks curved inward and slightly backward. Anterodorsal margin slightly concave near the beak, a little convex opposite the distal teetli; anterior end a little narrowed, obtusely rounded; ventral margin broadly and evenly rounded with a very faint undulation posteriorly; postero-dorsal margin a little convex, sloping less than the anterior, and turning up at the end so as to form a slight, hardly distinct rostrum. The linge-plate is rather large and thiek, especially distally on each side, becoming narrow and turning upward at the beak, where it is interrupted by a small, rather deep resilial pit, which is bordered interiorly by a thickened extension of the hingemargin forming a sort of shelf, the whole constitnting a broadly triangular chondrophore with the pit near its apex. The anterior series of teeth contains twelve, of which three or four proximal ones are very small, and form a series which curves upward, exterior to the chondrophore, and terminates at the smperior margin of the shell; the teeth
become large, strong, and thick distally, with broad V -shaped bases separated by deep pits. In the posterior series, which is a little the longer, there are eleven teeth corresponding in form and arrangement with those of the anterior series. The exterior surface is regularly sculptured with prominent, sharp, concentric, raised lines separated by wider intervals. Interior very glossy. Muscular scars and pallial line not visible. Exterior sculpture clearly seen through the shell.
Length, 4.2 mm .; height, 2.8 mm .
One valve, among Foraminifera, station 2150 , N. lat. $13^{\circ} 34^{\prime} 45^{\prime \prime}$, W. long. $81^{\circ} 20^{\prime} 10^{\prime \prime}$, in 382 fathoms, 1884.

ORTHOYOLDIA Verrill and Bush, 1897.
Orthoyoldia Verrill and Bush, Amer. Journ. Sci., III, pp. ant, 62, Janaary, 1897.
Type.-Orthoyoldia scapina (Dall).
Shell oblong, gaping, blunt or rounded at both ends, without a distinet rostrum; no carina. Pallial sinus large and broad. Teeth numerous in both series. O. scapina (Dall), from off Brazii and 0 . solenoides (Dall) from the West Indies.

## MEGAYOLDIA Verrill and Bush, 1897.

Megayoldia Verrill and Busii, Amer. Journ. Sci., III, pp. 55, 62, fig. 17, Jannary, 1897.

Type.-Megayoldia thracireformis (Storer).
We have established a new generic group for this large and wellknown species, which has sometimes been referred to Yoldict and sometimes to Portlandia. No closely allied species is known. It is probably the largest known species of this family and is remarkable for its broad, short, compressed form, with a very short, blunt, indefinite, posterodorsal rostrum, and with a low radial ridge, ending in a posteroventral marginal lobe. The chondrophore is remarkably large and strong, concave, striated within, and projects much within the margin of the hinge-plate. The pallial sinus is large and deep. In ontline it somewhat resembles typical Portlandia, but differs in being broader, flatter, and gaping at both ends, and in having a strongly developed external ligament. From Toldia it also differs in the last character, as well as in outline, but agrees with it in its compressed gaping shell.

The postero-ventral margin of the mantle forms a pouch-like protrosion, corresponding to the radial ridge. The siphon tubes are long and united; the posterior pallial tentacle is long and slender. The palpi are very large. The palpal tentacles originate from the body-wall at the base of the outer palpi; they are long and thick, with a large furrow on one side.

## MICROYOLDIA Verrill and Bush, 1897.

Microyoldia Vemerle and Bush, Amer. Journ. Sci., 11I, pl. 5f;, 62, Janaars, 1897.
Type.—Microyoldia regular is (Verrill).
Shell small, tightly closed, veneriform, with the anterior end shortest and with the beaks turned forward. A posterior marginal ligament in a distinct groove, contimed under the beaks. Hinge-plate and teeth rather strong; the anterior series of teeth the shorter, forming a marked angle with the posterior series. Resilium supported by a relatively large and strong chondrophore, placed on the surface of the hinge plate, distinctly behind the beakis and at the proximal end of the posterior series of teeth. Pallial line indistinct.

The curions little shell for which this genus is proposed is remarkable for its form and the size and position of the cartilage and chondrophore, as well as for its few blunt teeth. If we are correct in our conclusions as to the anterior and posterior ends, the beaks turn forward as in Tindaria. The principal reason for considering the longer end posterior is the existence of a well-formed ligament and groove along that end and not on the shorter one.

MICROYOLDIA REGULARIS (Verrill).
(Plate LXXVIII, figs. 5, 6.)
Yoldia regularis Verrile, Trans. Conn. Acad., VI, pp. 228, 279, 1884.
Microyoldia regularis Verrill and Busir, Amer. Journ. Sci., III, p. 56, figs. 5, 6, January, 1897.
This species closely resembles the very yomng of ITegayoldiat thraciceformis (Storer) Verrill and Bush, in the character of the hinge. Specimens of the latter measuring 3.51 mm . in length have the relatively large, concave, cartilage-plate just before the beaks, which curve strongly backward and are nearer the center of the shell, and the teeth are more mmerous and more slender.

In $M$. rogularis the shell is cordate ovate or veueriform. The beaks curve strongly toward the short (anterior?) end. There is on this end a sumken lumular area defined by a slight groove which indents the hinge-margin. The anterior (?) part of the hinge-margin is thickened and incurved along the lmule and bears an inner ridge and four or five, small, blunt feeth of which the proximal two project above the margin in a dorsal view, the others are low and rather obscure. Under the beak the hinge-plate is thickened, simons, edentulons for a short distance; back (?) of this there is a large, thick, oblique, concave chondrophore which occupies the whole breadth of the hinge-margin and projects inward beyond it as a shelf-like border; beyond this there is a series of six or seven prominent, blunt teeth. The external ligament lies in a distinct grove along a large part of the edge of the longer (posterior?) dorsal margin and runs under the beak, but facles ontin front of it. The pallial sims is not visible, consequently it is not possible to decide which is the anterior end.

But oue specimen from station 199, off Thatchers Island, in 95 fathoms, 1878 , has been referred to this species, besides the type speeimens (No. 38!20) station 1093, off Marthas Vineyard, in 349 fathoms, 1882.

## YOLDIELLA Verrill and Bush, 1897.

Foldiella Verrill and Bu'sh, Amer. Journ. Sci., III, pp. 55. 6.3, Jamary, 1897.

## Type.-Toldiellu lucida (Lov̌én).

This group includes a large number of small, mostly deep-sea species with glossy, iridescent, ovate, and usually wedge-shaped shells, nearly always having a slight antero ventral sinuosity, which feebly defines an obscure, blunt, rostal region, without any definite carination. The shells do not gape, but close tightly except that at the rostral angle of some species there may be a slight divergence. The internal cartilage, which is often relatively large, occupies a simple notch which interrupts the hinge-margin more or less completely and generally shows externally in a dorsal view; the notch usually terminates within, on the inner or inferior surface of the linge-plate and is often bounded within by a slight ridge. A weak external ligament is present on the posterodorsal margin. A relatively small pallial sinus has been observed in several of the species, but is usually indistinct. The siphon tubes as observed in a ferw of the species, are slender and united for more than half their length.

The following are some of the species: V. lucida (Loven) Verrill and Bush, Y. iris Verrill and Bush, and var. stricta Verrill and Bush, Y. inflata Verrill and Bush, Y. inconspicna Verrill and Bush, and I. jeffieysi (Hidalgo) Verrill and Bush, off Cape Hatteras, North Carolina, northward; Y. dissimilis Verrill and Bush, north of Cape Hatteras, North Carolina, northward; Y. fruterna Verrill and Bush, off Chesapeake Bay, northward; Y. minuscnla Vervill and Bush, and I. subequilatera Terrill and Bush, off Delaware Bay, northward; I. frigida (Torell) Verrill and Bush, and I. curta Verrill and Bush, off Marthas Vineyard, northward; I. subangulata Verrill and Bush, and Y. lenticula (Möller) Verrill and Bush, var. umblict Verrill and Bush, Gulf of Maine; Y. expansa (Jeffreys) Verrill and Bush, off Grand Banks; J. pachia Verrill and Bush, southern; I. hoylei (Smith) Verrill and Bush, North Pacific.

## YOLDIELLA LUCIDA (Lovén) Verrill and Bush.

## (Plates LXXYII, tig. -2; LNXX, tig. 3.)

[^17][^18]Shell small, swollen, subovate, with a posterior angle, smooth, or more or less striolate, iridescent. The umbos are but little prominent, in front of the middle; the beaks interrupted or obliterated by the dark central cartilage which occupies a relatively large notch intersecting the entire thickness of the hinge-margin. The antero-dorsal margin is convex with the edge a little expanded; it slopes rapidly from the beak to the anterior end which is obtusely rounded; the ventral margin is broadly and regularly curved nearly to the posterior end where there is a slight protrusion corresponding to a faint undulation of the surface; the posterior end is somewhat wedge-shaped, a little compressed and tapered, and makes a distinct but obtuse angle where it joins the dorsal margin in line with a rounded posterior ridge running from the convex part of the umbos; just below the angle the margin is usually convex or subtruncate and without any definite lower angle; the posterior dorsal margin slopes less rapidly than the anterior, is nearly straight with the edge compressed and a little expanded into a thin keel which is usnally slightly convex in the middle. The hingemargin is strong, somewhat prolonged, scarcely angulated in the middle; the part in front of the chondrophore is well-arched and bears, in the largest specimens, nine or ten, sharp, prominent, angular teeth, of which two or three nearest the beak are quite small; the posterior portion is nearly straight, a little longer and narrower than the anterior and bears about eleven thin, sharp, erect teeth, counting one or two minute proximal ones; a thin smooth margin extends outside both series of teeth. The cartilage-pit is relatively large, in the form of a notch, and euts through the hinge-margin into the substanee of the beak itself; it is occupied by a dark brown resilinm which usually shows plainly externally. Just in front of the cartilage-pit on its border within the series of teeth, there is a small conical, tooth-like process in both valves. The ligament is thin and delicate. Externally the shell is covered with a glossy, yellowish, or pale olive epidermis which reflects brilliant prismatic colors; the surface is marked by faint lines of growth and frequently also with fine concentric grooves or sulci, especially toward the ventral and anterior margins; in many specimens these are absent.

Length of one of the largest specimens, 7 mm .; height, 4.25 mm .; breadth, 3.2 mm .

Found in small numbers, at many stations, between N. lat. $43^{\circ} 39^{\prime}$,
W. long. $69^{\circ} 22^{\prime}$, and N. lat. $35^{\circ} 12^{\prime} 10^{\prime \prime}$, W. long. $74055^{\prime} 15^{\prime \prime}$, in 22 to 516 fathoms, 1872-1885.

The most prominent character of this species is the relatively large size of the cartilage-pit which intersects both the hinge-margins and the beaks and is therefore plainly visible from the exterior. In outline it is similar to I. iris and I. inflata but is more pointed and narrower posteriorly than either of them. They differ also in having much smaller cartilage-pits and in the number of the teeth.

Specimens formerly identified as Yoldia obesa Stimpson, agree perfectly with authentic specimens of lucida sent by Doctor Friele from Spitzbergen. As none of the species known to us agree sufficiently well with the description and figure of Leda obesa Stimpson, for us to decide definitely as to its correct position, unless we are to consider the figure a very incorrect representation, we prefer to let it remain doubtfully, as a synonym of Y. lucidu, where Jeffreys and others have placed it.

## YOLDIELLA IRIS, new species.

(Plates LXXX, figs. 1, 2; LXXXII, fig. 11.)
Shell small, thin, rather delicate, long-ovate or ovate-elliptical, with the beaks in front of the middle, not much swollen; surface smooth, or nearly so, with brilliant iridescence. The antero-dorsal margin is convex and slightly arched, sloping gradually to the obtusely rounded and slightly produced anterior end; ventral margin very broadly and evenly curved; posterior end obliquely ascending, obtusely pointed or rounded at the tip with a slight dorsal angulation; postero-dersal margin slightly convex, sloping but little, pinched up into a thin, rather prominent keel. The umbos are small and prominent with the beaks small, curved inward and backward, closely appressed to the margin. The epidermis is grayish or greenish yellow, smooth and shining; the surface is brilliantly iridescent, covered with faintly marked, fine, concentric lines, most distinct near the ventral margin and anteriorly; under the lens these appear like faint, close undulations over most of the surface. Escutcheon defined by a well-marked depression.

The hinge-margin is thickened and forms a very obtuse angle at the beaks; the posterior portion which is only slightly curved distally is longer than the anterior which is nearly straight. In the largest specimens there are twelve or thirteen acute erect $V$-shaped teeth in each series, including one or two minute, proximal ones. The resilial pit is minute, situated on the inner face of the thin edentulous hinge-plate, beneath the beaks, and faces ventrally so that it is scarcely visible in a front view and but partially interrupts the hinge-plate. Outside the series of teeth, on both sides of the beak there is a smooth, raised margin.

Length of one of the larger specimens, 7.5 mm . ; height, 5 mm .; from beak to posterior end, 4.5 mm .

Found in considerable mumbers, at abont forty-five stations, between N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ} 35^{\prime} 30^{\prime \prime}$, and N. lat. $35^{\circ} 12^{\prime} 10^{\prime \prime}$, W. long. $74^{\circ}$ .5 $7^{\prime} 15^{\prime \prime}$, in $20 \frac{1}{2}$ to 781 fathoms, $1872-1886$.

This species is more elongated and more regularly elliptical than any of the allied species; the hinge-margin is also less angulated.

A single specimen (No. 74325 ), station 43, off Cape Sable, in 90 fathoms, 1877, at first thonght to be a distinct species, differs from the typical form in being more oblong with the ventral margin less curven, the posterior end more evenly rounded with only a slight indication of a superior angulation, so that the shell has a pretty regular, narrow elliptical form. In all other respects, however, it agrees well with the ordinary form. This specimen, which receives the varietal name stricta, is figured on Plate LXXX, fig. 1.

Length, 5 mm . ; height, 3 mm .; breadth, 1.3 mm .; length from beak to posterior end, 3 mm .

## YOLDIELLA INFLATA Verrill and Bush.

## (Plates LXXX. fig. 8; LXXXII, figs. 5, 6.)

Yoldia Tucida Verrill, Trams. Conn. Acad., VI, p. 279, 1884 (in part).
Yoldiella infata Verbill and Inesir, Amer. Jourı. Sci., III, p. 56, figs. 3, 4, 11, January, 1897.

Shell small, swollen, rather short, subovate, with the posterior end broad, angulated postero-dlorsally; beaks at about the anterior third; surface smooth. Anterodorsal margin regularly convex and sloping rapidly to the anterior end which is evenly rounded, very obtuse, and passes insensibly into the evenly curved ventral margin which is decidedly convex, although the degree of convexity varies considerably in different specimens; the posterior end is obliquely subtruneated, with an obtuse enve below and an obtusely rounded angle at its upper extremity where it joins the nearly straight postero-dorsal margin. The umbos are full and well-rounded but not very prominent; the beaks are small, directly incurved, appressed to the margin. There is no distinct lunnle but the margin is slightly pinched up in a small crest both before and behind the beaks. The ligament is delicate and shows slightly on both sides of the beak. Epidermis pale olive yellow or straw color; surface smooth, shining, reflecting prismatic colors, showing more or less distinct lines of growth which sometimes become regular, concentric, very fine striations, especially anteriorly. Hinge-margin well developed, moderately broad and considerably thickened, forming an obtuse angle at the beak where it is thin, encroached upon by the beak and interrupted by the cartilage-pit; the two portions are nearly equal in length, the anterior somewhat arched, the posterior nearly straight, each having a thin, smooth border above the teeth, about equal in breadth to the linge-plate. In the largest specimens there are nine to eleven (most fiequently ten) rather stout, angular teeth and about ten very similar posterior ones; the cartilage-pit is suall and
just beneath the beak, forms a notch which completely interrupts the hinge-margin.

Length of one of the largest specimens, 6 mm .; height, 4.5 mm , thickness, 3 mm .; from beak to posterior angle, 4 mm .

Found in considerable nmmbers, at abont twenty stations, betiveen N . lat. $41^{\circ} 53^{\prime}$, W. long. $65^{\circ} 35^{\prime}$, and N. lat. $355^{\circ} 9^{\prime} 50^{\prime \prime}$, W. long. $74^{\circ} .57^{\prime} 40^{\prime \prime}$, in 516 to 1,608 fathoms, 1883-1886. Several live specimens, at station 2079 , in 75 fathoms.
This species is closely related to Y. lucidu (Lavén), from which it is easily separated by its shorter, broader, more swollen form, its strongly curved ventral margin, and very distiuct postero-dorsal imgle. It is shorter and has a broader posterior end than most of the related species. The resilium is not visible externally.

## YOLDIELLA SUBANGULATA, new species.

(Plates LXXVII, fig. 3; LXXIX, fig. 6.)
Very similar to the preceding species in form but less pointer posteriorly and larger. The umbos are small, not prominent; beaks are small, directly incurved, appressed to the hinge-margin bnt not distinctly notched by the resilial pit. The antero-dorsal margin is convex, arched; the anterior end is a little produced, obtusely rounded; ventral margin evenly and broadly rounded, slightly prodnced posteriorly, forming an obscure obtuse angle as it merges into the posterior end which is obliquely subtrncated or a little inflexed in the middle, with a prominent dorsal angle; the postero-dorsal margin slopes lont little, and is nearly straight, with the compressed edges forming a slight keel, which is a little convex in the middle. A well-marked ridge runs to the postero-dorsal angle, and a less distinet one to the postero-ventral angle; between these there is a slight depression of the surface. Surface nearly smooth, lustrons, reflecting prismatic colors, and covered with faint lines of growth and a few ineonspicnons irregnlar sulci; epidermis pale olive yellow. The hinge-margin is narrow, very obtusely angled, and is interripted under the beaks by the small notch-like resilial pit. The anterior series of teeth is slightly arched and contains about seventeen teeth, including three or four minute proximal ones; the larger ones are high and sharp. The posterior series is a little longer and contains about eighteen, similar, but somewhat more slender teeth. A thin, smooth margin extends along outside both series. There is a small internal denticle at the front edge of the resilial pit. Pallial sinns narrow, considerably intlexed.

Length, 8 mm .; height, 5 mm .; thickness, about 4 mm .; from beak to anterior end, 3 mm . posterior end, 5 mm .

One live specimen was dredged by the Buche at station 46, N. lat. $43^{\circ} 3^{\prime}$; W. long. $70^{\circ} 4^{\prime}$, in 51 fathoms, 1874.

Proc. N. M. vol. Xx- 55

## YOLDIELLA JEFFREYSI (Hidalgo).

## (Plates LXXXI, fig. 5; LXXXIII, fig. 3.)

Leda lata Jeffreys, Amı. Mag. Nat. Hist., p. 431, November, 1876.
Leda jeffreysi Jeffreys, Proc. Zoïl. Soc. Loudon, p. 579, pl. xlvi, fig. 2, Jme, 1879.-Smitif, E. A., Report Voy. Challenger, Zoül. Lamellibranchiata, XIII, p. 234, 1885.

Not Yoldia jeffreysi Verrill, Trans. Comn. Acad., VI, 1. 229, 1884.
Shell small, ovate-elliptical, somewhat thick for its size, rather swollen, covered with a glossy, iridescent, brownish yellow epidermis. The posterior end is considerably the longer, somewhat narrowed, bluntly rounded without any distinet rostrum. Umbos rather prominent, somewhat swollen; beaks prominent, curved inward and backward. The anterodorsal margin is broadly convex, slopes a little and becomes continuous with the rather regularly eurved ontline of the rounded anterior end; ventral margin is broadly and regularly curved without any distinct flexure; the posterior end is obtusely rounded and not defined by any radial lines or ridges, with the dorsal margin nearly straight at first, usually slightly convex in the middle, and sloping gradually. The surface beneath the epidermis is nearly smooth but shows more or less distinct lines of growth, which sometimes have the form of fine parallel striations. The hinge-plate is thickened and rather strong; the two series of teeth are long and form a very obtuse angle at the beak; the anterior is somewhat the shorter and more oblique and a little curved. In our type specimen there are thirteen anterior teeth of which three or four proximal ones are very small; and fifteen posterior ones, including four or five small proximal ones; a somewhat larger specimen has fifteen in the anterior series and eighteen in the posterior. The two series are intermpted beneath the beak by a small, well-defined, concave, triangular resilial pit supported on the inner side by a distinct shelf-like projection.

Length of the type-specimen, 5 mm . ; height, 3.1 mm . Length of the largest specimen, 5.6 mm ; height, 4.2 mm .

Six separate valves, at three stations, between N. lat. $37^{\circ} 38^{\prime} 40^{\prime \prime}$, W. long. $73^{\circ} 16^{\prime} 30^{\prime \prime}$, and N. lat. $36^{\circ} 42^{\prime}$, W. long. $74^{\circ} 30^{\prime}$, in 727 to 1,423 fathoms, 18St-1886.

As all of our specimens are much larger than the measurements given by Jeffreys, they are referred to $Y$.jeffreysi (Hidalgo) with some doubt, although they appear to agree well with Jeffreys's figure of that species in form and in the character of the hinge.

YOLDIELLA LENTICULA (Möller) variety AMBLIA, new.
(Plates LXXX, fig. 9; LXXXI, fig. 4.)
Nucula lenticula Möller, Int. Moll. Græenl., p. 17, 1842.
Foldia abyssicola Torell, Spitzhergens Molluskfauna, p. 149, pl. r, figs. 4, a-b, 1859.

Portlandia lenticula G. O. Sars, Mollnsca Reg. Arcticio Norvegria, p. 39, pl. 4, figs. 10, $a-b, 1878$.
Ledu lenticula Jerfreys, Proc. Zoül. Soc., London, 1. 577, June, 1879.

Our speeimens, which are worn and imperfect, referred to this northern species, differ somewhat from the typical specimens from Spitzbergen, received from Doctor Friele. They are relatively shorter, higher, and somewhat less swollen, with a thicker and heavier shell. The posterior end is less produced and less tapered, so that it has a more ovate form. The hinge-teeth are stouter; the posterior series is shorter but contains the same number of teeth in specimens of similar size. With the amount of material that we have for examination, the differences, however, seem hardly sufficient to warrant the separation of our shells as a distinct species. We therefore propose the varietal name amblia for our specimens.

A few separate valves, at two stations, north of Cape Cod, in 110 to 122 fathoms, 1878-79.

## YOLDIELLA FRATERNA, new species.

(Plates LXXX, fig. 5; LXXXII, fig. 8.)
Yoldia frigida Verrill, Trans. Conn. Acad., VI, 1. 279, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885 (in part).

Shell small, thin, delieate, irregularly elliptical in form, the posterior end being a little the longer, unnsually broad, and slightly produced above, but not distinctly angulated, with a glossy, iridescent, yellowish green epidermis. Umbos a little swollen; the beaks small, scarcely prominent, and subcentral. The anterior end is broad, a little produced in the middle, and obtnsely rounded; the dorsal margin is nearly horizontal in the region of the teeth; distally, sharp, and convex, then sloping rapidly to the middle of the auterior end. The ventral margin is broadly rounded, expanding a little posteriorly and then ascending pretty rapidly to the posterior tip which is obtusely rounded superiorly; postero-dorsal margin slightly convex and nearly horizontal for the greater part of its length. The surface beneath the epidermis is marked only by faint lines of growth. The hinge-margin is thin, rather delicate, with the two series of teeth of nearly equal length and diverging from the beaks at a broad angle; each series contains about ten rather thin and delicate teeth, of which the one or two proximal ones are very small and rather indistinct. Beneath the beak the margin is attenuated and interrupted by a small, oblong resilium which occupies the entire thickness of the margin and a slight noteh in the beak. The pallial sinus is relatively rather large and deep, but in most specimens is invisible.

Length of the figured specimen, 4 mm .; height, about $2 \frac{1}{2} \mathrm{~mm}$.
A comparatively small number of specimens, at about twenty stations, between N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ} 35^{\prime} 30^{\prime \prime}$, and N. lat. $37^{\circ} 8^{\prime}$, W. long. $74^{\circ} 33^{\prime}$, in 90 to 1,608 fathoms, 1873-1886.

This is a deep-water form formerly identified by us as Yoldia frigida Torell.

## YOLDIELLA CURTA, new species.

(Plate XCVII, fig. 8.)
Phaseolus ovatus (?) Verrile, Trans. Conn. Acad., VI, p. 230, 1881; Expl. Aluatross. Report U. S. Com. Fish and Fisheries for 1883, 1. 576, 1885 (not Neguenza).

Shell small, short-ovate, rather swollen in the middle, with rather prominent umbos, somewhat inequilateral, the posterior end the longer and slightly produced. Beaks small, incurved, with a slight posterior twist and a little separated from the margin. The dorsal margin is nearly straight medially, both before and behind the beaks, anteriorly it merges gradually into the broadly rounded anterior end, which usually has an obscure, blunt angulation in the middle; ventral margin broadly and evenly rounded, merging gradually into the more abrupt curve of the posterior end which is a little tapered. but obtusely rounded without any distinct rostrum or angulation; the postero-dorsal margin is a little prominent, pinched up and couvex, with a considerable slope, so that the tip of the shell is but little above the middle. The surface is polished and somewhat iridescent, marked only by fine, irregular lines of growth. Epidermis pale greenish or brownish yellow. There is a relatively very large resilium, appearing yoke-shaped or wide W-shaped in the separated valves, and covering a relatively long, edentulons space beneath the beaks. The teeth are compressed, oblique, imperfectly $V$-shaped, especially posteriorly, and but slightly elevated. There are six or seven in the posterior series, of which the proximal ones are rather indistinct; and four distinct and two or three indistinct ones in the anterior series. In a dorsal view five are visible above the margin behind the beak and four before. They are not very long and rather blunt, with the distal side sloping and the side next the beak a little incurved and concave.

Length, 2.6 mm .; height, 1.8 mm .; thickness, about 1 mm .
A few live specimens, at three stations, between N. lat. $41^{\circ} 11^{\prime} 30^{\prime \prime}$, W. long. $66^{\circ} 12^{\prime} 20^{\prime \prime}$, and N. lat. $39^{\circ} 38^{\prime}$, W. long. $70^{\circ} \mathscr{2}^{2} 2^{\prime}$, in 499 to 1,290 fathoms, 1883-1886.

This species somewhat resembles I. frigida in form, but it is relatively shorter, higher and less distinctly rostrated. Its hinge is also quite different. The present species is peculiar in having fewer and blunter teeth and a much larger resilium than most of the related species.

## YOLDIELLA PACHIA, new species.

Shell very broad, oval, considerably swollen in the middle, with the length and height nearly equal; nmbos rather prominent. The posterior end is narrowed and slightly produced, but not defined by any groove or carination. The dorsal margin is very obtusely angulated, anteriorly it is convex and slopes pretty rapidly to the broadly and evenly rounded anterior end; posteriorly it is nearly straight at first, then slopes gradually to the posterior end. The ventral margin is very
broadly rounded and slightly produced in the middle; it joins the curve of the posterior end with a scarcely perceptible incurvature in some specimens; the posterior end is obtnsely romded and situated abont midheight of the shell. The dorsal edges of the valve are thin and a little pinched up, but there is no distinct lumule and only a very narrow ligamental furrow. The epidermis is polished and somewhat iridescent, and marked with fine, somewhat irregular lines of growth, in some places showing faint, microscopie, radial striations. Color of the dead valves, brownish yellow. Hinge-phate strong, narrow near the beak, wide distally, strongly angled, with the outer edge naked and rather broad, especially anteriorly. Teeth large and prominent distally, with about three small proximal ones; about eight in the anterior and ten in the posterior series. The resilial pit is a distinct, triangular fossette, or chondrophore, on the face of the margin, covering its whole breadtl, and bordered internally by a thickened edge which canses an excurvature of the margin. There is a distinct marginal external ligament and furrow, or escuteheon.

Length, 4.6 mm .; height, 4.8 mm .
Three separate valves, among Foraminifera, at station 2385, N. lat. $28^{\circ} 51^{\prime}$, W. long. $88^{\circ} 18^{\prime}$, in 730 fathoms, 1885.

In outline this species resembles I. curta, but differs in its wider and stouter hinge-plate, more numerons and more highly developed teeth, and especially in the form and structure of the resilial pit.

## YOLDIELLA INCONSPICUA, new species.

## (Plate LXXIX, figs. 3, п.)

Shell small, thin, delicate, compressed, subovate; posterior end a little produced and narrowed medially. Surface lustrous and iridescent. Umbos scarcely prominent; beaks small, projecting but little above the dorsal margin. The antero-dorsal margin is slightly convex and nearly horizontal at first, then slopes gradnally to the evenly rounded anterior end; ventral margin broadly rounded, slightly swollen posteriorly, ascending more rapidly to the narrow and bluntly rounded posterior end; postero-dorsal margin nearly straight toward the beak, then slightly convex and sloping very gradually. The surface is covered with fine, pretty regular, concentric grooves and raised lines, visible only under the microscope. Epidermis thin, shining, iridescent, greenish yellow. The hinge-margin is thin and delicate, nearly straight; the two series of teeth form a very obtuse angle at the beaks and are interrupted, for a considerable space, by the resilium which does not lie in a distinct pit. The ligament shows as a delicate, continuous marginal line, both in front of and behind the beaks. The teeth are small, oblique, V-shaped. In the anterior series there are abont six distinct ones with one or two minute proximal ones; in the posterior, about seven distinct ones with one or two rudimentary ones near the beak.

The pallial sinus is rather wide and moderately deep, but is invisible in most specimens.

Length of the largest specimen, 3.6 mm ; height, 2.3 mm .
A number of specimens, at about fifteen stations, between N. lat. $42^{\circ} 33^{\prime}$, W. long. $69^{\circ} 55.5^{\prime}$, and N. lat. $35^{\circ} 12^{\prime} 10^{\prime \prime}$, W. long. $74^{\circ} 57^{\prime} 15^{\prime \prime}$, in 100 to 705 fathoms, $1878-1886$.

This species is distinguished from Yoldiella frigida, and most of the other small species which it resembles, by its narrower, or lower, and more compressed form, more delicate shell, straighter dorsal margin, and the more central prolongation of the posterior end. It is apparently more nearly related to the smaller species, I. minusculu, than to any other. The latter has a smaller, shorter, and more swollen shell, more convex ventrally, with the hinge-margin somewhat more angulated.

## YOLDIELLA MINUSCULA, new species.

(Plate LXXIX, figs. 2, 7.)

Toldia jeffreysi Verrill, Trans. Comn. Acad., VI, pp. 229, 279, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885.

Shell minute, broad-ovate, covered with microscopic, pretty regular concentric striations, with a very lustrous, somewhat iridescent, yellowish epidermis. The two ends are nearly equal in length; the posterior somewhat narrowed and obtuse at the end, the anterior wellrounded. The umbos are not prominent and the beaks are very small and project but slightly above the margin. The antero-dorsal margin is slightly convex at first, and nearly horizontal, and passes gradually into the curve of the anterior end; ventral margin is broad and nearly uniformly convex; the posterior end is a little produced in the middle and forms there a slight obtuse angle; the posterodorsal margin is a little convex and nearly horizontal at first and then slopes rather rapidly to the tip. The hinge-margin is thin and delicate; the two series of teeth lie nearly in a straight line but the anterior one is a little oblique, so that they form a very wide angle at the beaks where the resilium entirely interrupts the hinge-margin forming a wide notch without any definite pit or shelf; the teeth are small, very oblique, and only slightly prominent; there are only about five in the anterior and six in the posterior series.

Length, about 2.3 mm ; height, about 1.5 mm .
Only a few specimens, at four stations, between N. lat $41^{\circ} 53^{\prime}$, W. long. $65^{\circ} 35^{\prime}$, and N. lat. $38^{\circ} 27^{\prime}$, W. long. $73^{\circ} 2^{\prime}$, in 705 to 1,290 fathoms, 1883-1885.

This very minute species may, with a larger series, prove to be the young of some of the preceding species.

## YOLDIELLA SUBEQUILATERA (Jeffreys).

Leda subequilatera Jeffrbys, Proc. Zö̈l. Soc., London, p. 579, pl. xlvi, fig. 3, 1879.
Yoldia subequilatera Verrill, Trans. Conn. Acad., VI, pp. 229, 279, 1884 (in part); Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885 (in part).
Leda subequilutera Dall, Bull. Mns. Comp. Zoïl., XII, p. 252, $18 \times 6$.
Yoldia subequilatera Dall, Bull. U. S. Nat. Mus., No. 37, p. 4t, 1889.
Several live speeimens (No. 35204), from station 2037, N. lat. 380 53', W. long. $69023^{\prime} 30^{\prime \prime}$, in 1,731 fathoms, 1883 , have been referred to this species. Although younger or smaller than Jeffreys's type, they agree very elosely with his figures and deseription. The shell is very small, very thin and transparent, polished, lustrous, but searcely iridescent and marked only by mieroscopic lines of growth. It is rather compressed, nearly elliptical in form, with the beaks prominent above the dorsal margin and turned almost directly inward. Both ends are obtusely rounded and nearly equal in length, so that it is impossible to determine which is anterior and which is posterior by the external characters; oue end, supposed to be the anterior, is however slightly broader than the other. There is no distinet ligament visible exterually. The hinge plate is nearly straight, the two series of teeth forming but a slight angle. Interior not seen.

Our specimens measure from 1.5 to 2.5 mm . in length. South to Grenada, in 92 fathoms.-Dall.

## YOLDIELLA EXPANSA (Jeffreys).

## (Plate NCYII, fig. 3.)

Leda expansa Jeffreys, Ann. Mag. Nat. Hist., p. 431 , Norember, 1876; Proc. Zö̈l. Soc., London, p. 580. pl. xlvi, fig. 4, June, 1879.
Not Joldia expansa Verrile, Trans. Conn. Acal., VI, p. 279, 1884.
Shell oblong-ovate, nearly equilateral, with the posterior end a little more broadly romed than the anterior: both regularly obtuse. Both dorsal margins are slightly couvex and slope but little. The hinge-plate is moderately wide, gently arehed, with sharp dorsal margins, and is completely interrupted in the middle by a deep, angular notel for the resilimm which is rather large and dark and is attached to the inner surface of the shell below the beak. In the right valve, there are nine posterior teeth, including one or two very small proximal ones, separated from the margin by a rather wide, smooth space; those in the middle of the series are long, with tapered, aeute tips which are bent upward and toward the beaks, and at base are V -shaped. In the anterior series, which is a little the longer, there are ten teeth, ineludiug two or three very small, proximal ones; the larger ones are nearly erect with the tips less inclined than those in the posterior series; they are separated from the margin ly a plain space about as wide as
the teeth. In the left valve, there are eleven anterior and nine posterior teeth. The surface of the shell is dull yellowish green, only slightly iridescent, and covered with irregular lines of growth which, in some places, form irregular raised lines. The umbos are but little prominent; the beaks are small and turn backward.

Length, 3.6 mm .; height, 2.5 mm .
One specimen (No. 78363), station 2697, N. lat. $47^{\circ} 40^{\prime}$, W. long. $47^{\circ}$ $35^{\prime} 30^{\prime \prime}$, in 206 fathoms, 1886.

This species is peeuliar in its nearly equilateral, elliptical form, with the dorsal margins gently convex and only slightly sloping both sides of the beaks, and especially in its large resilial noteh which ents entirely throngh the linge-plate. It agrees pretty closely with Jeffreys' type, but the latter was much smaller and his figures and diagnosis are too imperfect to make its identity certain.

## YOLDIELLA FRIGIDA (Torell).

## (Plate LAXIX, fig. 4.)

Toldia frigida Verrill, Trams. Conn. Acad., V', 1. 573 , pl. xlyv, fig. 2, 1882; VI, p. 279, 1884 (in part) ; Expl, Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576,1885 (in part).

A very few specimens, at about ten stations, between N. lat. $43^{\circ} 5^{\prime}$, W. long. $70^{\circ} 11^{\prime} 30^{\prime \prime}$, and N. lat. $39^{\circ} 53^{\prime} 30^{\prime \prime}$, W. long. $71^{\circ} 13^{\prime} 30^{\prime \prime}$, in 88 to 312 fathoms, 1874-1881.

## YOLDIELLA DISSIMILIS, new species. <br> (Plates LXXVIII, fig. 8; LNXXII, fig. 7.)

Yoldia expansa Verrill, Trans. Comn. Acall, VI, p. 279, 1884; Expl, Albatross, Re-
port U. S. Com. Fish and Fisheries for 1883, p. 576,1885 (not of Jeffreys).
Shell small, oblong-ovate, nearly equilateral, with the anterior end the broader and bluntly rounded, the posterior eud somewhat narrowed medially and bluntly rounded, without any distinet angulation. Umbos somewhat prominent; beaks small and strongly ineurved. Surface straw-colored, not lustroas, eovered with fine concentric lines. Anterodorsal margin but little curved, sloping very gradually to the anterior end which is enrved nearly in the are of a eircle; ventral margin very broadly rounded with a very slight obtuse angulation behind the middle; postero-dorsal margin slightly excavated just behind the beaks, then sloping very gradually to the obtnse posterior end. The hingemargin is moderately stout; the two portions form a very wide angle at the beak with the anterior, which faces obliquely downward, considerably the more arched. In the center the margin becomes very thin and is interrupted by the resilium which oceupies a deep notch and an internal shelf of considerable size, sitnated far back and directed downward to such an extent that it is only partially visible in a direct front view; there are abont eleven or twelve anterior, and eight to ten poste-
rior acnte, curved, $V$-shaped teeth; at the proximal end of the posterior series, in the left valve, there is an oblong, prominent, tooth-like process, mueh larger than the adjacent teeth. Three or four of the distal teeth, on each side, are decidedly large, prominent and acute with the tip curved outward, but the size decreases regularly toward the center. There is a well developed dark ligament, visible externally, both before and behind the beaks. The surface is covered by relatively rather large, distant, concentric ridges and furrows, easily visible under a lens, which are everywhere covered by very regular microscopic lines and grooves of about equal width.

Length of the largest valve, 4.25 mm . ; lieight, 2.8 mm .
A few specimens, at four stations, between N. lat. $39^{\circ} 49^{\prime}$, W. loug. $68^{\circ}$ $28^{\prime} 30^{\prime \prime}$, and N. lat. $36^{\circ} 47^{\prime}$, W. long. $73^{\circ} 9^{\prime} 30^{\prime \prime}$, in 1,451 to 1,685 fathoms, 1853-18S6.

This species is remarkable for its oblong-ovate form and very regular concentric seulpture, consisting of fine ridges and furrows which are in turn everywhere covered with regular microscopic lines. This species was at first thonght to be I. expansa (Jeffreys) which it resembles in form, but additional specimens and more careful study show that the species are very distinct. In I. expansa the hinge-margin is much straighter, the teeth fewer and different in form, the resilial pit very different, the two ends of the shell more nearly equal, and the sculpture quite different.

Our species differs considerably from the typical forms of Yoldiella in having a more oblong form with both ends evenly rounded, a welldeveloped ligament, and a more evident resilial fossette or chondrophore which, however, is situated decidedly below the hinge-plate. The existence of a peculiar tooth-like process adjacent to the resilial notch would be a character of considerable importance were it constant, but the specimens show great variation in its development; in some. it is even almost abortive. These distinctive characters, althongh important, seem hardly worthy of generic distinction.
Subfamily MALI,ETLNAE.

$$
\text { MALLETIA Desmoulins, } 1832 \text { (restricterl). }
$$

Malletia Verrill and Bush, Amer. Journ. Sci., III, pp. 56, 63, Jannary, 1897.

## Type.-Malletia chitensis Desmonlins.

We have restricted this group to those species having a nearly smooth, somewhat compressed, oblong or elliptical shell, blunt posteriorly, without any definite rostrum or carination. The carinated and rostrated species that have been placed in it will thus be referred to Neilo H. and A. Adams. The resilium is wanting, or else represented by a special part of the ligament, external to the teeth. The ligament is well developed and prominent. The siphon tubes are long and united nearly to the tips.

The subgenus Pseudomalletia, proposed by Fischer for M. obtusa, was based on an erroneous description of the siphon tubes.
The following are some of the known species:
M. chilensis Desmonlins, Valparaiso (Type); M. obtusa (Sars) Möreh, from off Cape Fear, North Carolina, northward; M. polite Verrill and Bush, off Delaware Bay; M. ubyssorum Verrill and Bush, off Chesapeake Bay; M. cuncatu Jeffreys, North Atlantic; M. pallidn Smith, Mid-Sonth Atlantic; M. errouana Smith and M. dunkeri Smith, Pacific; and M. bellardii Segnenza, fossil.

MALLETIA OBTUSA (M. Sars) Mörch.
(Plate XCVII, fig. 4.)
Foldia obtusa G. O. Sars, Remarkable Forms of Animal Life, p. 23, pl. iIf, figs. 16-20, 1872.
Malletia obtusa G. O. Sars, Mollnsea Reg. Arctica Norvegite, p. 41, pl. 19, figs. 3, $a-b, 1878$.-Jeffreys, Proc. Zö̈l. Soc., London, p. 586, June, 1879.-Verrill, Trans. Conn. Acad., VI, pp. 226, 280, 1884; Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885.-Smitif, E. A., Report Voy. Challenger, Zö̈l. Lamellibranchiata, XIII, p. 245, 1885.-Dall, Bull. U. S. Nat. Mus., No. 37, p.46, 1889.—Busir, Bul. Mus. Comp. Zoül., XXIII, p. 234, 1893.-Locard, Campagne du Caudan", Annales de l’Université de Lyon, p. 202, 1896.-Verrill and Bush, Amer. Journ. Sci., III, p. 57, fig. 9, 1897.

The soft parts of several specimens, rather poorly preserved in alcohol, have been examined. They have a large foot with an ovate disk pointed in front and minutely crenulated. The siphon tube is rather long and slender, in some cases not entirely retracted within the shell; it appears to contain both the branchial and anal tubes which are closely united quite to the simple tips; at the inner base, there is a well-marked siphonal septum. The gills are smail, elongated, pointed posteriorly, and have the structure usual in the family. The palpi are rather large, elongated, with revolute margins; the palpal tentacle is very long and slender, and in the contracted state varionsly bent with the edge much convoluted. No pallial tentacle was found at the base of the siphon.

In our collection there is a large series of this species; the form is pretty constant and in nearly all cases is more oblong than the European species, as figured by G. O. Sars. The small specimens are compressed while the large ones are a little swollen. The umbos are small, but slightly elevated; the beaks are very small, turned directly inward, and are almost in contact with the margin, so that they are generally worn away in the larger specimens. Directly under, and partly in the beaks, and also cutting more or less into the thickness of the external side of the hinge-margin, there is a swall notch, or shallow excavation, which is occupied by a special portion of the iigament that probably represents a remmant of a degenerated resilium. The true ligament is well developed and prominent for about one-half the length of the hinge-margin, then becomes abruptly thinner and nar-
rower; its groove is narrow and inconspicnous. The hinge-margin itself is rather thin and bears very numerous, erect, $V$-shaped, acute teeth which nmmber, in the large specimens, about sixteen or seventeen in the anterior series and about thirty-two or thirty-three in the posterior, including a number of small proximal ones; beneath the beaks there is a smooth, edentulous space, often a little thickened at the inner margin and projecting a little inward in the middle, and continning inside the series of small proximal teeth on each side. In some cases this thickened border seems to arise anteriorly and to pass under the posterior series, as a slight fold; in other cases it is continued directly from one series to the other. The posterior series is nearly straight and about twice as long as the anterior which is strongly curved and distally somewhat recedes from the thin dorsal margin. The anterior end of the shell is rather short and evenly rounded; the posterior is about twice as long, a little wider owing to a slight ventral expansion, compressed and obtusely rounded or subtruncated at the margin, but without any distinct carination or angulation. The pallial sinus is very broad and deep, extending nearly to the middle of the shell. The inner surface is smooth, white or grayish white. The exterior is smonth, except for the delicate lines of growth, and covered with a thin, brilliantly iridescent epidermis which, in live specimens, is pale yellowish green, but in dead valves is pale straw color.

Our larger specimens measure about 15 or 16 mm . in length and 9 or 9.5 mm . in height.

Found at many stations between N. lat. $41^{\circ} 28^{\prime}$, W. long. $65^{\circ} 35^{\prime}$, and N. lat. $35^{\circ} 16^{\prime}$, W. long. $75^{\circ} 2^{\prime} 30^{\prime \prime}$, in 516 to 1,781 fathoms, 1883-1857.

## MALLETIA ABYSSORUM, new species.

## (Plate XCVII, fig. 7.)

Shell small, not much compressed, lustrous, iridescent, subovate, mot gaping, decidedly inequilateral, with the posterior end the longer, broader, obtusely rounded, without any distinct rostration. Umbos rather prominent, rising above the outline of the dorsal margin, with small beaks turned backward at the tip. Lunule and escutcheon abortive. The short antero-dorsal margin is slightly coneave, and slopes rapidly to the slightly angulated anterior end; the ventral margin is very broadly and evenly convex, the curvature receding somewhat posteriorly, so that the greatest height of the shell is somewhat back of the middle, posteriorly there is a slight extension of the edge corresponding to an indistinct radial ridge; the posterior end is very broad, obtuse, not angulated, with the dorsal margin nearly horizontal, slightly convex, compressed and forming a slight angle where it joins the posterior curve. A very slight groove defines a very faint escutcheon, along the edge of which the teeth can be seen throngh the substance of the shell. The surface is polished, brilliantly iridescent, and is marked by faint, raised, concentric lines, or ridges parallel with the lines of growth;
near the ventral margin these become more elevated, clearly defined, and are separated ly wider, slightly concave grooves. The hinge-plate is rather thin and delicate, regularly curved, without any angle at the beaks, with the posterior portion considerably the longer. There is a small, median, specialized ligament which ocenpies a lunate, or nearly semicircular notch in the hinge-plate directly beneath the beak, which does not extend through its entire width although it is here quite narrow. The posterior ligament is pretty well developed and extends from the beak, where it is closely comnected with the median portion, nearly to the distal end of the series of teeth, and occupies a distinct marginal groove; the portion nearest the beaks, opposite the smaller teeth, is thicker and darker colored than the rest and projects slightly, in a dorsal view; a delicate, inconspicuous portion continues a little in front of the beak, in a thin groove. The median portion of the ligament is so closely connected with the posterior portion that it appears to lee a specialized, thickened portion of it, but is evidently homologous with the resilium of other genera; it is sitnated, however, ontside the series of teeth and mnst serve as a ligament. The larger teeth are delicate, subacute, $V$-shape, compressed in a direction parallel with the dorsal margin, with deep pits between them. There are about ten in the anterior series, including three or four, very small, searcely raised ones next the beak; and fourteen in the posterior series, of which the seven distal ones are decidedly larger than the rest, the tenth to the thirteenth being the largest; about four, next the proximal end of the series, are like small, rounded tubercles or granules withont a $V$-shape form; following these are three of intermediate form, increasing in size distally, the seventh being more or less V-shaped; these smaller teeth form a series along the inner edge of the hinge plate. An edentulons ridge, abont as long as the space occupied by the first three teeth, extends from the first tooth to the ligament-pit and is continuons with a similar, thinner ridge running below the ligament-pit to the anterior series of teeth. The pallial simus is of moderate size and triangular in form.

Length, 5 mm .; height, 4 mm .
One live specimen (No. 52159), station 2566, oft Chesapeake Bay, in 2,620 fathoms, 1885.

## MALLETIA POLITA, new species.

(Plate LAXXII, fig. 10.)
Shell of moderate size, irregularly ovate, somewhat swollen, the rentral region convex and the posterior end somewhat produced with a short rostrum. Epidermis light yellow, lustrous and iridescent. Umbos not prominent, beaks small, strongly incurved, only slightly elevated above the margin. The anterodorsal margin is slightly convex and slopes gently to the short, obtusely rounded anterior end which is slightly angulated in the middle; the ventral margin is strongly con-
vex, a little produced in the middle, and with a slight incurvature toward the posterior end, below the rostrum; the posterior end is narrowed and produced into a short obtuse rostrum with a nearly straight dorsal margin. The surface is covered with rather fine, somewhat meven, concentric lines and undulations. The hinge-margin is but little thickened; the anterior portion is the shorter and the more curved and forms a very obtuse angle with the posterior portion which is nearly straight. There are about twelve conspicuous, rather elevater, slaap teeth in the anterior series besides three or forr minute, proximal ones: and more than twenty in the posterior series, the number being indeterminable owing to an injury to the margin close to the beak. The external ligament is large and conspicuous and ocenpies a marginal groove extending the entire length of the posterior series of teeth. There appears to have been no chondrophore, but whether the line of teeth was continuous is uncertain.

Length, 14.5 mm . ; height, 9 mm .
One valve (No. 75972), statiou 2718 , N. lat. $380 \because 44^{\prime}$, W. long. $71052^{\prime}$, in 1,569 fathoms, 1886.

NEILO Adams, 1858.
Neilo H. and A. Adams, Genera of Recent Mollnsea, II, 1. 54! ; III, pl. Cxxvi, figs. 7, 7a, 7b, 1858.-Verrill and Bush, Amer. Jomrn. Sei., 11I, 1יI. 57, 63, January, 1897.

## Type.-Neilo cumingii Adams.

The type species of this genus has an oblong shell, with a straight postero-dorsal margin and a well-defined rostrum, bounded beneath by a pronounced furrow and a margiual indentation, while more ventrally, the margin protrudes somewhat, the ponting of the margin corresponding with special lobes of the margin of the mantle. N. cumingii from New Zealand is concentrically grooved, but N. gomiura (Dall) ${ }^{1}$ from off the coast of Eenador is smooth or nearly so.

## NEILONELLA Dall, 1881.

Saturnia Seguenza, Nnculidi terziarie merid. d'Ital., R. Accad. Lincei, I, p. 1178, 1877 (not Schrank, 1802).
Leda (section Neilouella) Dall., Bull. Mus. Comp. Zö̈l., IX. p. 125, 1881; XII, p. 254, 1886. + Saturnia Dall, p. 263.
Neilonella Verrill and Bush, Amer. Journ. Sci., III, pp. 57, 63, January, 1897.

## Type.-Neilonella corpulenta Dall.

Shell small, swollen, short-ovate, with both ends obtuse; the posterior somewhat the longer, blunt at tip, without any distinct rostrum or carina. Exterior nsually concentrically grooved. Ligamental area not defined. Beaks usnally prominent and turned inward and slightly backward. Ligament well developed, extending under and before the beaks in a distinct groove, more prominent behind. Resilium very

[^19]minute or nearly abortive, occupying a slight notch in the dorsal margin under the beak, external to the series of teeth, which are interrupted only by a small, thin edentulons space. Pallial sinus small. Siphon tubes short. Labial palpi large, broad, creseent-shaped, with long tentacular appendages. Gills small, triquetral.

We consider this gronp worthy of generic rank. It appears to be more nearly allied to Malletia than to Yoldia or Ledf. We can find no generic chamaters to distinguish Dall's typieal species ( $N$. corpulentu) from N.pusio, which was the type of the section, Suturnia, proposed by Seguenza. They agree closely in form, external scnlpture, arrangement of the teeth, and structure of ligament and resilium. The name, Saturnia, being preoccupied by Schrank, 1802, we have adopted Dall's name for both of his sections.

The following species appear to belong here:
N. corpulentu Dall (type), and N. quadrangularis (Dall), West Indies; N. sericen (Jeffreys), Treland and Portugal; N. pusio (Philippi), Mediterranean and West Indies; N. subovata Verrill and Bush, from off Cape Hatteras, North Carolina, northward.

## neilonella subovata Verrill and Bush.

(Plates LXXX, fig. 10; LXXXII, figs. 3, 4.)
Yoldia sericea Jeffreys, var. striolata Verbill, Trans. Conn. Acad., VI, p. 226, 1884.-Verrill, Expl. Albatross, Report U. S. Com. Fish and Fisheries for 1883, p. 576, 1885.
Neilonella suborata Verrill and Busir, Amer. Journ. Sei., III, p. 57, figs. 7, 8, 22, Jannary, 1897.

Shell somewhat swollen, subovate, with the dorsal margin angulated and the umbos somewhat prominent. The anterodorsal margin is somewhat convex, pinched up at the edge, and sloped gradually to the evenly rounded anterior end; ventral margin is broadly and nearly evenly rounded throughout, without any simosity, and forms a blunt point at its junction with the postero-dorsal margin, which is nearly straight or slightly couver for the greater part of its length, with the edge thin and pinched up. The umbos are somewhat prominent and the beaks curve strongly inward aud incline a little backward at the tip. The ligament is well developed, dark brown, and as seen in a dorsal view, fills a narrow, lanceolate excavation in the margin just behind the beaks. In an interior view it is conspicnons behind the beaks and oceupies a curved noteh immediately under them, and extends forward for a short distance in a.thin, marginal groove. The resilium is abortive or nearly so; in many cases it appears to be represented by a miunte black speck, adherent to the ligament, and occupying a minnte indentation in the edge of the hinge-margin directly beneath the beak, external to the series of teeth. The hinge-margin is broad and rather strong, becoming very narrow below the beak hut without a distinct notch or chondrophore; the posterior portion is
nearly straight, the less oblique and considerably the longer, and forms a broad angle with the anterior. There are in the largest examples about elevell or twelve teeth in the anterior series, counting four or five very small proximal ones; and in the posterior series, fifteen or sixteen teeth of which the five or six proximal ones are minute. In many specimens the two series are not distinctly separated under the beak, in others there is a very minute, edentulous space in line with the minute ligamental notch. The largest teeth in the middle of each scries are very elongated, erect, acute, with the tips turned upward toward the margin. The surface of the shell is covered with very regular, concentric sulcations separated by narrow, evenly rounded ridges of about the same width; in most cases this sculpture is faint or nearly obsolete toward the postero-dorsal margin and on the umbos. In many specimens, a number of faint radiating strise run from the umbos to the antero-ventral margin, similar lines sometimes occur posteriorly. The epidermis is without much luster, of either greenish yellow, light yellow, or straw color, more or less iridescent, especially near the umbos. Along the dorsal margin the outline of the teeth can be imperfectly seen through the substance of the shell. The interior in fresh specimens is lustrous bluish white and in some cases is distinctly tinged with pale flesh-color. The museular and pallial impressions are usually indistinct but some specimens show a small, but distinet, angular pallial sinus.
The alcoholic specimens when dissected were found to have a short siphon and a large, stont foot with a broad disk having strongly crenulated edges. The labial palpi were long, erescent-shaped and the tentacle-like appendages arising from the outer bases of the external palpi were very long, slender, and coiled in a spiral. The gills were long, narrow, and prismatic, one on each side.

Length of one of the largest specimens, 6.5 mm .; height, 4.6 mm ; thickness, about 3.5 mm .
Young specimens about 2 mm . long are more equilateral than the adults and have the posterior end less produced and more evenly rounderl, the umbos decidedly prominent, and the surface covered with fine, regular, concentric grooves, the epidermis showing distinct iridescence.

Found in large numbers, at many stations, between N. lat. $42^{\circ} 47^{\prime}$, W. long. $61^{\circ} 4^{\prime}$, and N. lat. $35^{\circ} 9^{\prime} 50^{\prime \prime}$, W. long. $74^{\circ} 57^{\prime} 40^{\prime \prime}$, in $125_{2}^{1}$ to 1,731 fathoms, 1883-1887.
This species shows considerable variation in form when a large series of specimens from the same locality are compared. Some are decidedly more elongated and tapered posteriorly than the typical form, others are somewhat shorter and more regularly ovate with the posterior end blunter or more rounded; all agree essentially in sculpture and in the peculiar structure of the hinge and ligament.

This species has some resemblance to $N$. sericea Jeffreys, of which it
was formerly thonght to be a variety. It differs, however, in its larger size, more ovate form, the posterior end being more produced and tapered, and in its stronger sculpture. N. corpulenta Dall is narrower, more elongated, with more prominent beaks. N. quadranymlaris (Dall) is shorter and more triangular in form, with the postero-dorsal margin more oblique.
subfamily 'IINDARINAE Vemill and I3ush.
Cucullellina Fiscmer, Manuel (onch., p. 981,1887 (in part).
Tindarina Verrill and Busif, Amer. Journ. Sci., III, Pl. 58, 63, January, 1887.
The genus Tindaria differs so widely from Mralletia and other genera that it seemed necessary to establish a new subfamily for it.

In this group the shell is rather thick, short-ovate or veneriform, with the posterior end the longer, and with the beaks turned forward. The resilium is wanting. The ligament is well developed and prominent. The teeth are numerous, V -shaped, in two series which are frequently continuous proximally. There is neither pallial simus nor true siphons. The mantle is broadly open ventrally, but there is a separate anal or efferent orifice surrounded by small sense papilla. The palpi are large, with long, slender appendages. The foot has a large, terminal, cremulated disk.

This gronp agrees with Malletinar in laving no resilium, but the latter has well developed siphons and a pallial sinus.

TINDARIA Bellardi, 1875.
Tindaria Vermill and Búhh, Amer. Jonrn. Sci., III, pp. 58, 63, Jannary, 1897.
Type.-Tinduriu aruta Bellardi.
Several recent writers on these shells have regarded Tindaria as a subgenus of Malletia. In reality they form two widely diverse genera and have little resemblance except that in both the resilium is wanting. In typical Tinduria the shell is swollen, short-ovate or subcordate, without any rostration, with prominent umbos and with the beaks turned forward. In fact the shell may be described as veneriform. The surface is usually concentrically grooved. The series of teeth are often continnons medially. There is no pallial sinus.

A specimen of T. amabilis Dall ${ }^{1}$ from station 2385, among Foraminifera, in 730 fathoms, not very well preserved in alcohol, has the mantle closed for a short distance behind the anal orifice which is large and surrounded by twelve or more, rather large, unequal papillic, but does not appear to be capable of being protruded in a tubular form, unless a very short one. The mantle is otherwise freely opeu along the whole ventral margin to the oral area, with its edges nearly plain,

[^20]showing only very minnte papillie posteriorly．The foot is large and strong，with a broad，strongly crennlated and striated，concave disk， pointed in front．The gills are well developed and somewhat triquetral， The palpal teutacles are rather large，long，tapered，triquetral，strongly grooved，curved in sickle－shape．The palpi are rather broad and short．

The following are some of the known species：
T．arata Bellardi，and T．solida Seguenza，fossil．in the Italian ter－ tiary formation；T．cytheren Dall $=$ T．veneriformis（Smith），T．amabilis Dall，T．virens Dall，T．ucimulu Dall，T．cnneatu $($ Smith $)=$ T．smithii Dall，T．luta Verrill and Bush，all Florida and West Ludian species； and T．callistiformis Verrill and Bush，off＇Chesapeake Bay．

## TINDARIA CALLISTIFORMIS Verrill and Bush．

> (Plates LXXVIII, fig. 1: LXXX, figs. 6, 7.)

Tindaria cullistiformis Verrill aut Busif，Amer．Journ．Sei．．III．p．59，tigs．10， 20，21，January， 1897.

Shell small，stout，thick，regularly ovate，sculptured with very regu－ ular，fine，conceutric grooves，and having a broad，thick hinge－margin with a continnous line of teeth and no chomdrophore．Umbos swollen， beaks prominent，strongly curved inward and somewhat forward，with the nuclear shell（prodissoconch）smooth and glossy．The lunular area is somewhat excavated but has no definite boundary．Anterior end considerably shorter than the posterior，both equally and evenly rounded．Antero dorsal margin conves，sloping rather rapidly and forming a continnons curve with the anterior margin which is also contimons with the more broadly convex ventral margin：the poste－ rior end is evenly rounded，with the dorsal margin strongly convex， sloping gradually，without any definite angulation．The surface is covered with very regular，fine，close．concentric，rounded ridges，sepa－ rated by semicircular furrows abont twice their width，except ou the umbos where the two are abont equal．The inner vential margin is plain，sharp，and slightly beveled．The hinge－margin is wide and thick，narrowest just behind the beaks，gradually widening and thick－ ening toward both ends．The anterior portion is much the shorter and somewhat the wider and slopes more rapidly；along the narrow mid－ dle portion the teeth are quite small，but regular，transverse，and sep－ arated by narrow intervals；owing to the absence of a chondrophore， there is no detinite center，but in front of the tip of the beaks there are about eight teeth which increase rapidly in size and prominence， the four distal ones being large，elevated，and somewhat V－shaped； behind the beak there are abont twenty－three teeth，of which nine or ten proximal ones are small；they then commence to increase in size and length so that eight or nine are larger and higher than the rest； these are，however，smaller and more acute than the larger ones in the anterior portion；two or three distal ones are a little less elevated than
Proc. N. M. vol. xx-
those which precede them and a little difterent in form. Above the teeth there is a distinct and rather deep submarginal groove for the ligament which extends continuonsly both in front of, and behind the beaks. Behind the beaks there is a distinct rounded ridge rumning outside of, and panallel with the ligamental groove and terminating at the distal end of the row of tecth. ['allial line entire; 10 siphon; ana] opening separated, suromed by about twelve unequal papilla; elsewhere the open mantle edge is nearly plain: foot large with a crenate disk.

Epidermis pale yellowish brown ; interior glossy bluish white without pearly luster.

Length, 8 mm : lıeight, 6 mm ; thickness, about 4.5 mm .
A small specimen ( 3 mm . long, 2.5 mm . high) from station 2714 , is doubtfully referred to this species. Externally it is covered with very fine regular, concentric, raised lines and grooves, agreeing well with the corresponding umbonal portion of the type. The epidermis is thin, pale straw color. The outline is also similar but the posterior half of the shell is relatively a little broader, owing to a slight expansion of the postero-ventral margin. The beaks appear to be relatively less prominent. The external ligament is well developed both sides of the beaks, and is slightly thickened just under them. and fills a very slight notch in the edge of the hinge margin above the teeth. The hingeplate is relatively broad and strong, especially anteriorly. There are thirteen posterior and nime anterior teeth, the two series separated by a small edentulous space. Some of the distal teeth in the anterior series are unusually large and stout and exceed any of those in the posterior series. The pallial line is distinct and entire.

One live specimen (station ٌ.jib), N. lat. $37^{\circ} 23^{\prime}$, W. long. $63^{\circ} 8^{\prime}$, in 2,620 fathoms, 1855 . One, rery young, live specimen (station 2714 ), N. lat. $38^{\circ} \because 2^{\prime}$, W. long. $70^{\circ} 17^{\prime} 30^{\prime \prime}$, in $1, S_{2}^{\circ} 5$ tathoms, 1886.

This species is remarkable for its thick, firm shell, regular ovate form, and very even, concentric sculpture. In form and general appearance it resembles some species of Callista.

## TINDARIA LA'TA, new species.

Shell rather thick, somewhat compressed, broad-ovate, equilateral, narrowest in front of the beaks, the posterior end somewhat produced and very broad. U'mbos only slightly prominent. Beaks small, rather acute, turned directly forward and closely appressed to the margin. No lumle nor escutcheon. The antero-dorsal margin is nearly straight and slopes but little, but becomes a little convex and passes insensibly into the evenly ronnded curvature of the anterior end; the rentral margin is very evenly and broadly rounded but the eurve recedes as it passes backward so that the highest part of the shell is distinctly behind the middle; the posterior end is very evenly and broadly rounded without any angulation; the postero-dorsal margin is consid-
erably longer than the anterior and slopes pretty regularly and gradu－ ally from the beaks to the posterior extremity．The surface is covered mith very regular，rather coarse，rounded，concentric ridges separated by deep furrows of about the same breadth．The epidermis is light straw color，only slightly lustrous and scarcely iridescent．The linge． plate is large and strong，much elongated posteriorly，the two parts forming a very obtnse，curved angle at the beaks．The auterior portion is the broader，much the shorter，and bears about nine teeth，of which the three distal ones are much the larger and occupy abont one－half the length of the series，the proximal ones being very small．The pos－ terior portion is narrower and curved throughont；it bears seventeen or eighteen teeth of which seven or eight proximal oues are very small and acute．The hinge－plate becomes quite narrow under the beaks where the two series of teeth are interrupted by a very small edentu－ lous space，scarcely wider than the adjacent teeth．All the larger teeth are rather crowded and compressed in the direction at right angles to the line of the hinge so that they are only slightly V－shaped．Seen in a dorsal view they appear thin and not very prominent above the mar－ gin of the shell，when the tips are broken they often appear three－ lobed．The ligament is well developed and occupies a distinct，sub－ marginal furrow behind the beaks．The muscular scars are well marked，small and nearly round；the pallial line is interrupted at a point a short distance from the posterior musenlar scar but there is no visible simus．The interior of the shell is grayish white but not pearly； the ventral edge is slightly beveled．

Length of the largest specimen， 7 mm ．；height， 5.5 mm ．
Two specimens，among Foraminifera，at station 2355，N．lat． 280 51＇， W．long． $88^{\circ} 18^{\prime}$ ，in 730 fathoms， 188 i．

## TINDARIA CUNEATA（Smith）Dall．

> Malletia cuneata Smith，E．A．．Report Voy．Challenger，Zoül．Lamellibranchiata， XIII，p．247，pl．xx，figs．10，10a， 1885 （not Jeffrers）．
> Malletia（Tindaria）smithii Dall．Bull．Mus．Comp．Zoül．，NII，p．255， 1886.

A single young valve，among Foraminifera，at station 2655，N．lat． $27^{\circ} 2^{\prime 2}$ ，W．long．is $7^{\prime} 30^{\prime \prime}$ ，in 338 fathoms，1886．Off Grenada and the W＇est Indies，in 390 to 1,140 fathoms．－Smith and Dall．

As the species described and figured by Mr．Smith under the name of Malletiu cuneata is a true Tindaria，his mame does not conflict with the Malletia cmentu of Jeffreys which is a true Malletia，and therefore should remain unchanged．

## Subgenus TINDARIOPSIS Verrill and Bush， 1897.

Tindariopsis Velrillami Busif，Amer．Journ．Sr•i．，JIl．pp．59，63，Jannary， 1897.
Type．—Tindariopsis ayathidlu（Dall）．${ }^{1}$

[^21]This division was proposed for those species which have a short rostrum, lefined by a radial ridge and a furrow. The type has a wellmarked dorsal ligamental furrow and a small notch or "socket" under the beak for the specialized part of the ligament. It is uncertain whether it has a siphon and a pallial simus. In case these are present, it should form a distinct genus and be placed under Malletine.

ANALYTICAL TABLE OF RECENT SUBFAMILIES, GENERA, AND SUBGENERA OF LEDID.E AN1) NUCULII.E HERE ADOPTED.
A. Shell not gaping, short-ovate, subtrigonal, or ronnded; posterior end withont a rostrum; heaks usually curved backward; no siphon tulees nor pallial sinus.

Nuculide d'Orbigny.
B. Shell more or less trigonal, usually ohlique; posterior end usually shorter; beaks turned backward. N"uculiuce Verrill and Bush.
c. Teeth mumerons, transverse, $V$-shaped, forming two convexly arched or angnlated series; a distinct median chondrophore; no lateral teeth.

T'ucula Lamarek.
cc. Teeth few, not forming long series; a long lateral tooth in each valve; no median chondrophore

Nuculina d'Orligny
AA. Shell ovate, oblong or lanceolate; pesterior end generally the longer and usually more or less rostrated; siphon tubes and pallial simus generally present. Ledide II. and A. Aclams.
C. Cartilage or resilinm present, not closely mited with the external ligament.

Ledine H. and A. Adams.
a. Resilium supported ly a definite concave chondrophore extending inward to, or beyonl, the inner edge of the hinge-plate.
b. Shell not gaping unless at the end of the rostrom.
c. Shell distinctly rostrated and carinated posteriorly.

Leda Schumacher (sense extended).
d. Shell elongated and tapered posteriorly, rostrum long, bicarinate, hlunt ; ligamental area or escutcheon long and well-defined; pallial sims and siphom tubes developed

Leda (sense restricted).
dd. Shell shorter, swollen, ovate or oblong, posteriorly not much elongated; rostrum short, usually acute, unicarinate.
$e$. Shell orate, rostrum small, acnte; ligamental area or escutcheon distinctly bordered by a carin:i.
$f$. Rostrum short, subacute, snbmedian, defined below by a ventral sinnosity or emargination. ..................... Junoniu Seguenza $=$ Ledella Verrill and Bnsh.
ff. Rostrim short, dorsal, not defined below by a rentral sinuosity; posterodorsal margin concave; escuteheon sumken
.Inpiteria 13ellardi.
re. Shell ohlong, angular, sulitruncate, rostrm short, angular, dorsal, defined below by a marginal sinnosity : escutcheon well-defined.... Portlandia Mörch.
ece. Shell not rostrated, small, ovate or elliptical, ronnded at both ends, anterior end the shorter, no carina, lunule, nor escuteheon ; cartilage posterior, internymphal

Mieroyoldia Verrill and Bush.
bb. Shell oblong or lanecolate, compressed, nearly plain, more or less gaping at both ends; rostrum not well-defined; pallial sinns large and broad; tulues long, united.
g. Teeth transverse, -shaped, numerons, in two long series; chondrophore large, concave, projecting strongly inside the hinge-plate.

「oldít Mäller (sense extemded).
h. Shell large, compressed, rommded anteriorly, broalest posteriorly with a posteroventral protrusion and radial ridge; rostrmm shori, hroad, poorly defined; external ligament well seveloped, prominent both sides of the beaks, occupying a continuons furrow; no lumble nor escutcheon.

Megayoldia Verrill and Bush.
hh. Shell lanceolate or long-ovate, posteriorly narrowed and somewhat elongated, more or less sinuons below ; rostrum slightly defined, smooth or slightly carinate; external ligament ferbly developed........ . Foldin (sense restricted). hhh. Shell oblong, smooth, plain, blont and romnded at botio emls, withont any distinct carina, siunosity or rostrmm .............. Orthoyoldia Verrill and Bush.
hhhh. Shell thin, compressed, narrow-lanceolate or long-elliptical, nearls equilateral, and gaping at both ends: scnlpture oblique.

Adrana H. and A. Adlams.
hhhh. Shell hraline, oblong-ovate, broad posteriorls, concentrically sculptured, rostrum nearly obsolete ....................... Adranella Verrill and 1Bnsh.
gg. Shell thin, oblong, inequilateral, blunt at looth ends, not rostrated nor carinated: teeth few, lamellar. very oblique. Tspe, $S$, frethilis .leffreys.

Silicula Jeffreys.
fu. Shell small, nearly plain, not mneh rostrater nor carinaten; resilium withont a prominent chondrophore, situated in a notch in the hinge-margin, interrupting the series of teeth.

1. Tceth V-shaped, numerons in both series.
$m$. Shell oblong or subovate, blont posteriorly, with a slightly sinnous margin, sometimes subrostrate, not carinate................. Foldiella Verrill and Bush. $m m$. Shell regnlarly orate, rounded at hoth ends, not sinnons nor earinate, (?) no pallial simus
....Sarepta A. Adams.
2. Shell short-ovate, not simuous nor angulated; teeth few, ohliqne, not regularly V-shaped. Type, I'. aratus Segnenza.................. Phaseolus Seguenza. CC. No true resilinm; ligament well developed, often prominent behind the beaks which are usnally turned forward.
D. Siphon tubes aud pallial sinus present; teeth mostly $V$-shaped, in two long series, often interrupted by a median edentulons space.

Malletine H. and A. Adams.
o. Siphon tubes long; pallial simus large; shell elongated, gaping.
$p$. Shell oblong or elliptical, hunt posteriorly, not distinctly rostrate; series of teeth mequal; those in the auterior series fewer......... Malletia Desmonlins. $p p$. Shell long-ovate or oblong, broadly angulated and sinnous posteriorls; distiuctly rostrate and earinate: two series of teeth nearly equal.

Neilo H. and A. Alams.
oo. Siphon and pallial sinus small, shell ovate, not gaping; a rullmentary marginal resilium .............................................................eilonella ball. DD. Shell short-orate or subeordate, elosed at both ends, umbos prominent; ligament entirely external ; series of teeth generally continuons.

Tiuduriau Verrill and Bush.
s. Shell regnlarly orate, grooved, without rostrum or carina: lieaks turned forward; 110 pallial sinns. $\qquad$ Tinduria Bellardi. ss. Shell ovate, with a distinet posterior sinuosity and a short rostrum.

Tiudariopsis Verrill and Bush.

## Family SOLENOMY゙ID.モ.

## SOLEMYA GRANDIS, new species.

> (Plate LXXXVI, figs. 1, 2.)

Shell large, considerably broader anteriorly than posteriorly, dorsal margin in front of the beaks straight and thickened by an internal ridge and a strong epidermal fold. At the anterior end the valves gape widely, and the edge of each is divided into six or seven long, nearly regular, digitate processes of nearly uniform width, and obtusely rounded at the ends, separated by notches, rounded proximally. The
general ontline of this end is broadly truncate; the ventral margin is somewhat convex but slopes upward toward the posterior end and is nearly straight along the middle: the posterior end is short, evenly rounded, with the dorsal margin, behind the beaks, strongly ineurved; the large black ligament which ocenpies this area is continuous with the epidermis, so that its ontline forms a curve nearly in line with that of the anterior end, and shows but a slight angle, or lobe, at the outer end of the dorsal line. The umbos are thattened, and scarcely prominent. The whole surfice is covered with a thick, smooth, glossy epidermis, chestunt-brown in the young and brownish black in adult, which anteriorly is divided into several rather broad digitations that are shorter and somewhat wider rentrally, their length diminishing from the middle of the anterior end to the ventral margin, along the middle of which there are uo digitations, but short and broad ones again appear posteriorly. The shell is sculptured by radiating ribs and furrows which are but slightly developed on the middle region but become large aud strong auteriorly and smaller and closer posteriorly. On the anterior part these ribs are broad and that, separated by wide, flat-bottomed, furrows often nearly as wide as the ribs; on the middle area, the firrows are shallow and rounded while the intervening spaces are flat, sometimes broad, at others narrow, this region appearing comparatively smonth, some specimens showing but slight indieations of grooves and ribs; posteriorly these are somewhat more numerons, narrower, often about equal in width. In specimens of medium size, there are from six to eight of the large anterior furrows and as many ribs; the edges of the latter are somewhat elevated above the middle portion and these thickened margins extend out along the edges of the digitations which otherwise corespond to the furmors. Intermally the shell is white, moderately thick, the anterior portion oblong with obtusely trumeated end, the dorsal and ventral margins nearly parallel, and the posterior much narrower and tapered to an obtnsely romed end, with the dorsal margin excavated for the ligamental anea. The surface shows distinct but not very prominent grooves and ridges corresponding to the exterior ones; at the antenior end the margin shows slight lobes, corresponding to the intervals between the epidermal digitations. The anterior muscular sear is large and rounded, the posterior one is smaller aud subovate. Anteriorly the hinge-mangin is thickened in both valves, roming from near the beak nearly to the end; posteriorly it is more strongly thickened by a simous callus to which the ligament is attached, while under and just in front of the beak the margin is excavated for the reception of the cartilage which continues forward in a groove and is contimons with the boad, dorsal, epidermal margin which unites the two valves throughout their length. The posterior ligament and anterior cartilage appear to hlend just beneath the beaks; the commencement of the cartilage is, however, indicated by a slight noteh in the callus-margin, in both valves, and the ligament appears
to extend formard in a point between the two sides of the cartilage. There are no transverse costic or buttresses for strengthening the hingemargill.

Entire length, including epidermal lobes, $5 t$ mm. ; entire height, opposite the beaks, 22 mm. ; height of the anterior third, $26 m m$; breadth, in the middle, 12 mm . ; length of longest digitations, about 10 or 12 mm .; length of the shell itself, 12 mm . ; height at the middle, 1.5 mm . ; length from beak to anterior end, 30 mm .; to posterior end, 14 mm . Frag. ments of specimens more than twice as large as the one measured have been taken. In one of these the lieight of the shell withont the epidermis is 2.5 mm .

Two good specimens and some fragments, at four stations, between N. lat. $39^{\circ} 58^{\prime} 30^{\prime \prime}$, W. long. $70030^{\prime}$, and N. lat. $37^{\circ}-{ }^{\prime} t^{\prime}$, W. long. $\bar{t} t^{\circ} 1 \bar{\sigma}^{\prime}$, in 300 to 1,600 fathoms, $1850-1884$.

6. Foldiella subangulata Verrill and Bush, p. הbis. Exterior of right valve of type specimen from station 46 Fache ; $\times 7 \frac{1}{2}$.
7. 「oldiella minuscula Verrill and Bush, p. 夂it). Interior of left valve of suerimen No. $38415 ; \times 22$.
8. Ledd bushiana Varrill and Smith. p. 85t. Exterior of right valve of type sperinen No. 35729; $\times$ alont 3.
9. Cuspidarite formose Verrill and Bush, p. 803. Internor of lrft valve of trpe specimen No. $78313 ; \times 3$.
10. Martesiella, fratilis Yerrill and Bush, p. $7 \overline{7}$. Exterior of right valve of a specimen from ne:n station $2566 ; \times 6$.

Plate LXXX.

Fig. 1. Soldiellu iris Yerrill and Bush, variety stricta Verrill and Bush, p. 8bt. Exterior of right valive of type specimen No. 74325 : $\times$ about 13.
2. Foldiella iris Yerrill and Bush, 1. 863 . Interior of a left valve from station $895 ; \times 11$.
3. Toldiella lucida (Lovén) Verrill aml Bush. p. Eb1. Exterior of left valve of specimen No. $73173 ; \times$ ahont $6 \frac{1}{2}$.
4. Adranclla casfa Verrill and Bush, p. 85s. Interior of a leftralve from station $2150: \times 11$.
5. Toldifla fraterna Verrill and Bush, p. 867. Exterion of left valvo of trpe specimen from station 947 ; $\times$ about 13.
6. Tindaria callistiformis Verrill and Bush, 1. 8R1. Hinge of right vialve of type specimen No. $52536 ; \times 8$.
7. The same. Turned up to show shape of teeth.
8. Soldiclla infata Verrill and Bush, p.86t. Exterior of luft valve of tyle specimen No. 38417 ; $\times$ ahont $5 \frac{1}{2}$.
9. Soldiclla lenticnla (Mïller) variety amblia Verrill and Bush, p. \&ib. Fxterior of left valve of a specimen from station $186 ; \times 10$.
10. Neilonella suborata Verrill and Insh, j. 878 . Exterior of lett valve of specimen No. $34826 ; \times 11$.

## Plate LXXXi.

Fig. 1. Lédella para Varrill and Bnsh, p. 857. Interion of a right valve No. 7836 ; $\times 25$.
2. Nrucnla granulosa Verrill, p. 853. Hinge of right valve of type sperimen No. 38451 ; $\times$ about 16.
3. Necula cancellata Jeffreys, p. 85t. Hinge of right valve of sperimen No. 45795 ; $\times$ abont 13.
4. Foldiclla lenticula (Mäller) variety amblia Virmill and linslı, p. Shb. Interior of a right valve from station $186 ; \times 12$.
5. Ioldiella jeffivegsi (Hidalgo), p. 8t6. Interior of right vialve of suerimen No. 789.5s; $\times$ abont 13.
6. V'ucula proxima say (?) variety orata Verrill aud Bush, p. sio. Hinge of right valve of specimen No. $78467 ; \times$ about 16 .
7. Ledella messumensis (Seguenza) variety subleris Verrill andBush, p. 8atb. Hinge of left valve of specimen No. 35212: $\times$ about 16.
8. Nucule suborata Verrill and Bush, p. 852. Interior of left valve of type specimen No. 40474: $\times$ about 13. Showing resilinm attached to pit.
9. Ledrlla messamensis (Segnenza), p. E5. Hinge of left valve of specimen No. $52156 ; \times$ about 16.

## I'hate LXXXII.

Fig. 1. Leda caudata (Donovan), p. א.5. Interior of right vialve of spreimen No. 3820: ; $\times$ about $5 \frac{1}{2}$.
2. Leda prorulu (Miiller), p. 855. Hinge of right valve of sperimen No. 73077 ; $\times$ abont $\overline{2} \frac{1}{2}$.
3. Neilonclla suborata Verrill and Bush, p. 87x. Hinge of left valve of sperimen No. $31326 ; \times$ abont 10.
f. The same. Thmed up to show shape of teeth.
5. Foldiella inflata Verrill and linsh, 1, s64. Hinge of a left valve No. 35075 ; $\times$ about 10 . Turned up to show shape of teeth.
6. The : ame. Front view.
7. Toldiella dissimilis Verrill and Bush, p. 大i?. Hinge of a loft valve No. 38416; $\times 20$.
s. Yoldiclla fraterna Verrill and Bush, p. \&is. Hinge of ripht valve of type specimen from station 947; $\times 20$.
9. Lerla bushiana Verrill, 1. 8. 4. Hinge of botlı valves of trpe specimen No. $35729 ; \times$ about $6 \frac{1}{2}$.
10. Malletia polita Yerrill ant Bush, p. 876. Hinge of a left valve No. 78792 ; $\times$ abont $6 \frac{1}{2}$. Some of the teeth are broken away just behint the beak.
11. Toldiella iris Verrill and Bush, 1. 863. Hinge of left valve of a yonng specimen; $\times 20$.

## Plate LXXXIII.

Fig. 1. Crenella frayilis Verrill, p. 847. Interion of right valve of type specimen No. No. $41543 ; \times$ abont 3.
2. The same. Hinge of another larger, imperfect specimen No. $40676 ; \times$ abont 3.
3. Foldiclla jeflreysi (Hidalgo), p. 866. Exterior of a left valvo No. 78958; $\times$ about 13 .
4. Limopsis profundicola Yerrill and Bush, p. 847. Interior of a right valre of a roung specimen No. $38143 ; \times$ abont 3 .
5. Nucula suborata Verrill and Bush, p. 822. Exterior of left valve of type specimen No. $40476 ; \times$ about 13.
6. Abra longicallis (Scacchi) varicty americand Verrill and Bush, p. 7is. Interior of right valve of sperimen No. $52170 ; \times$ alout 3.
7. The same. Hinge of both valves of the same speeimen; $X$ abont $\&$.

## Plate LNXNIV.

Figs. 1 and 2. Chlamys bencdicti Verrill and Bush, 1. 834 . Exterior of hoth valves of a young specimen fomm among Foraminifera; $\times 20$.

## Plate LAXXV.

Fig. 1. Cyelopeeten leptalens Verrill, j. 839. Portion of upper or lett valve of trpe specimen No. 38413 to show character of sculpture: $\times 10$.
2. Cyclopecten naums Verrill and Bush, p. 837. Exterior of lower or right valve of a yonng specimen from station $2965 ; \times 5$.
3. The same. Exterion of left valve of a larger specimen from the same station $; \times 5$.

1. The same. Hinge of the same valve; $\times 13$.
2. Cyelopecten pustulosus Verrill, p. 839. Portion of left valve of sperimen No. 4876.5 to show elraracter of sculpture $; \times 10$.
3. The same. Piece of a left ralve of another specimen No. 48761 to show variation in form of pustules; $\times$ about 13 .
4. Camptomectos granlaudica (Sowerby) Verrill, p. 837. Nxterior of right valver of specimen No. 78387 ; $\times 5$.

Fig．8．Cyclopecten subimbrito Verrill and Bush，p．840．Portion of left valve of specimen No．48762 to show rhanacter of scnlpture：$\times 10$ ；
9．The same．Exterior of left valve of speciusen No． $4 \times 66$ from of Nova Scotia， in 190 fathoms ；$\times 3$ ．
10．Cyclopecten pustulosus Verrill，p．839．Exterior of left valve uf trpe specimen No． $4 \times 764 ; \times 3$.
11．The same．Exterior of right valve of another specimen；$\times 3$ ．

## ILate LXXXVI．

Fig．．Solemya grandis Verrill and Bush，1）．885．Exterior of left valve of trpe specimeи No． 5134. ；$\times 1 \frac{1}{2}$.
2．The same．Interior of right valve of an imperfect specimen No． $10103 ; \times 1 \frac{1}{2}$ ． Epidermal fringe restored from other specimen．
3．Cryptodon（．（ximulus）pygmans Verrill and Bush，p． 7 ！！．Exterior of left valve of specimen No． 78368 from station $2397 ; \times \underline{2}$ 。
4．The same．Interior of right valve of a smaller specimen from the same station；$\times 2.2$.
5．Niucula cuncrllata Jeffreys，p．85t．Exterior uf left valve of sperimen No． $45795 ; \times 13$.
6．Chlamys costcllata Verrill and Bush，p． 835 ．Exterior ui right valre of type specimen No． $5: 471 ; \times$ 。

## Plate LXXXYII．

Fig．1．Poromya subleris Verrill，variets microdonta Dall，p．813．Hinge of a left valve No． $78799 ; \times 5$.
2．Ferticardia aramlifora（Verrill）Dall，p．816．Interior of a left valre（type specimen）No． 44 ベ3s：$\times 4$.
3．Lyonsiella subquadratu（Jetireys），p．817．Interior of a left valve No．78800； $\times 10$ ．
4．Periploma＂ffinis Verrill aud Bush，p．S2．2．Exterior of right valve of type speeimen from station 873；$\times 4$.
5．Periploma undulata Verrill， 1 ． 823 ．Extrrior ot left valve of type sperimen No． $44840 ; \times 4$.
6．I＇ropetmasium thalassinnm（1）all）Verrill，p．Xt1．Exterior of uper or left valve of a specimen from station $949 ; \times 16$ ．
7．Cryptoton（Aximulus）foruginosus（Forbes），p．793．Interior of right valve of specimen No． $34860 ; \times 12$ ．
8．The same．Interior of left valve of the same specimen．

## Plate LiNXViII．

Fig．1．Crimptolon croulimensis（Jeffreys）Smith，variety altus Verrill amd linsh，p． 787. Exterior of a left valve from Eastport，Maine， $1870 ; \times$ abont 8.
2．The same．Interior of a light valve from the sime locality $; \times$ about 8 ．
3．Cryptodon planns Verrill and Bush，p．788．Interior of left valve of type specimen from station $254 ; \times 14$ ．
4．The same．Exterior of light valve of the same specimen．
5．Tucula proxima Say（？）variゃty orate Terrill and Bush，p．852．Esterior of left valve of sperimen No． 73167 ；$\times$ about 12.
6．Macoma inflata Dawson，p．778．Exterior of left valve of specimen No．52427； $\times 3$ ．
7．Konerlia brevis Verrill and Bush，p． 821 ．，Exterior of left valve of speci－ men No． 40232 ；b，interior of right valve of another specimen No． 45884 ； $\times 4$ ．
8．Tucula gramulosa Verrill，p．8is．Exterior of lelt valve of type specimen No． $38451 ; \times$ about 26.

## Phate LXNXIX.

Fig. 1. Cryptolon obsoletus Verrill and bush, p. 789. Exterior of right valve of a specimen from station $943 ; \times$ abont 20 .
2 . The same. Interior of left ralve of the same speeimen.
3. Leptarinus minutus Verrill and Bush, p. 797 . Hinge of left valve of trpe specimen No. 45686: $\times 45$.
4. The same. Hinge of right valve of the same specimen.
5. The same. Interior of the same valve; $\times 30$.
6. Cryptodon plicatus Verrill, p. 786 . Interior of left valve of a young specimen No. $41826 ; \times 9$.
7. Cryptodon (A.rinulus) breris Verrill and Bush, p. 790. Exterior of left valve of trpe specimen from station 2208 ; $\times$ about 22 .
8 . The same. Interior of right valve of the same specimen.
Plate NC.
Fig. 1. ('ryptodon (Axinulus) incqualis Verrill and Bush, p.791. Exterior of right ralve of type specimen from statiors $98-99 ; \times$ abont 10 .
2. The same. Interior of left valve of the same specimen.
3. Cryptodon croulinensis (Jeffieys) Smith, 1, 786. Interior of left valve of a specimen from stations $62-65 ; \times$ about 13 .
4. The same. Exterior of right valve of the same specimen.
5. Aximoton elliptieus Verrill and Bush, p. 796. Exterior of right valve of type specimen No. 35175: $X$ about 13.
6. The same. Interior of left valve of the same slecimen.
7. Tellimya ferruginosa (Montagu), p. 783. Interior of left ralve of specimen No. $49588 ; \times 20$ a, Cartilage.
8. The same. Interior of right valve of the same specimen.

Plate NCI.
Fig. 1. Cryptodon insignis Verrill and Bush. p. 785. Interior of a left valve No. 52733 from station $2499 ; \times$ about $1 \frac{1}{2}$.
2. The same. Exterior of a left value from the same station; $\times$ alont $1 \frac{1}{2}$.
3. Montacutu triquetra Verrill and Bush, 1. 782 . Interior of right valve of type specimeu from station 2307: $\times 24$.
4. Montacnta cuneatu Verrill and Bush, p. 782 . Exterior of right valve of a specimeu from station $2278 ; \times 17$.
5. Cryptodon equalis Verrill and Bush, p. 788 . Hinge of both valves of a specimen from station 18 Bache: $\times$ about 5 .
6. The same. Exterior of left valve of specimen No. $74302 ; \times$ abont 5 .
7. Cryptodon (Axinulus) oratus Verrill aud Bush, p. 793. Interior of left valve of tepe specimen from station $949 ; \times 35$.
8. Ficlliella nitida Verrill, p. 778 . Interior of left valve of specimen No. 37971; $\times 14$.

## Plate XCII.

Fig. 1. Axinodon ellipticus Verrill and Bush. p. 796 . Hinge of left ralve of type specimen No. 35175 ; $\times$ abont $26 \frac{1}{2}$.
2. Limopsis sulcata Verrill and Bush, 1. 845. Interior of a right valve from statiou $2199 ; \times 4$.
3. Cryptodon (Arimulus) simplex Verrill and Bush, p. 791. IIinge of right valve of type specimen from station 1093 ; $\times$ abont 13 .
4. The same. Interior of left valve of the same specimen.
5. Axinopsis orbiculata Sars, variety inequalis Verrill and Bush, p. 794. Interior of left valve of type specimen from Eastport, Maine, $1872 ; \times$ about 13 .

Fig. 6. The same. Hinge of hoth valves of the samu specimen: $\times$ abont 26 .
7. Montacnta bidentata (Montagu) variety tenuis Verrill and Bush, 1. 779. Interior uf a riglit valve from station 2277; $\times$ abont 13.
8. Montucuta bidutata (Montagn) varicty fiagilis Verrill and Bnsh. p. 780. Interior of a right valve No. $46134 ; \times 17$.
9. Montacuta mata Jetfites. 1. 781. Interior of a right vialve No. $16136 ; \times 20$.
10. The same. Interior of a left valve No. $46137 ; \times 20$.

## Blate $\operatorname{loClil}$.

Fig. 1. Cryptodon (Aximulus) oratus Verrill and Bush, p. 793. Hinge of hoth valves of type specimen from station $949 ; \times 45$.
2. Kelliopsis elevata (Stimpson) Verrill and Bush, p. T8t. Hinge of a right valve No. 74333 fro:n Naushon; $\times 30$. a, Resilimm ant ussicle.
3. The same. Hinge of another right valve from the same station, to show variation; $\times 30$.
4. The same. Hinge of both valves of another specimen from the same station ; $\times 30$.
5. Montacuta cuneata Verrill and Bush, p. 782. Hinge of looth vialves from station 2978; $\times 30$.
6. Montaruta tnmidula Jeffress, 1. 781. Hinge of a left valve No. 35.412: $\times 30$. a, Resilinm and ossicle.
7. Montacuta bidentata (Montagu), p. 779. Hinge of a right valve No. Tł328 from Nanshon; $\times 30$.
s. The same. Hinge of both valves of a smaller specimun from the same station; $\times 30$.
9. Montacuta striatula Verrill and Bush, p. 780. Hinge of a left valve from station $2276 ; \times 30$. Hinge of a light valve from station $2273 ; \times 30$.
10. Kelliella mitida Verrill, p. 778. Hinge of both valves of specimen No. 37:77; $\times 12$. Right valve turned down, left turned up

## Plate Ne'ly.

Fig. 1. Montacuta tumidula Jeftreys, 1. 781. Interior of a left valve No. 35412 from station $2103 ; \times 20$. $\quad$, Resilimm and ossicle.
2. The same. Interior of a right valve from the same station: $\times 0$.
3. Kellia suborbicularis (Montagu), p. 779. Interior of left ralve of a sperimen from off Salem, Massachnsetts, $1 \times 77 ; \times 10$.
4. The same. Interior of right valve of the same specimen.
5. Montacuta casta Verrill and Bush, p. 781. Exterior of a left valve from station $2283 ; \times 20$.
6. Montacuta bidentata (Montagn), 1, 779. Interior of a right valve No. 74328; $\times$ abont 13 .
7. Kelliop*is elevata (Stimpson) Verrill and Bush, p. 784. Interior of a right valve No. it333 from Naushon: $X$ about 13 . a, Resilimm and ossicle.
8. The same. Exterior of a left valve from the same station ; $\times$ abont 13 .

## Plate XCV.

Fig. 1. Lyousia granulifera Verrill and Bush, p. 818. Exterior of a left valve (type specimen) No. 52561 ; $\times$ about $2 \frac{1}{2}$.
2. Terticordia gramulifera (Verrill) Dall. 1.816. Hinge of a left valve (type sperimen) No. $44838 ; \times 8$.
3. The same. Hinge of both valves of a fully grown specimen No. $78679 ; \times t$. Turned up to show ossicle, a.
4. The same. Hinge of a right valve of another specimen No. $78929 ; \times 6 \frac{1}{2}$.

Fig. 5. Clidiophorat imormuta Yerill and Bush, 1. 819. Hinge of both valves of specinen No. 49760 from station 327 ; $\times$ abont $2 \frac{1}{2}$.
6. The same. Exterior of a left valve of a specimen from the same station; $\times$ abont $2 \frac{1}{2}$.
7. Lyomsiella cordata Verrill aud Bush, p. N18. Hinge of left valve of type specimen No. $52540 ; \times 8$. a, Ossicle; $b$, liqument.
8. The same. Exterior of right valve of the same specimen; $\times$ abont 4 .
9. Limopsis sulcata Verill and Bush, p. 845. Hinge of a right valve from station 2199 ; $\times$ abont $10 \frac{1}{2}$.
10. Nucula rerrillii Dall, 1. 853 . Hinge of left valve of specimen No. 45752 ; $\times$ about 26.

## Plate xCVI.

Fig. 1. Limopsis sulcata Verrill and Bush, p. 845. Exterior of a right valve from station $2199 ; \times 16$.
2. Choristodon (?) cancellatus Verrill, p. 778. Hinge of a left valve (type specimen) No. $44839 ; \times 16$.
3. The same. Exterior of the same valve; $\times 6$.

## Plate XCyII.

Fig. 1. (ilomms mitens Jeftreys. p. 818. Interior of left valve of specimen No. Tぶ®4; $\times 12$.
2 . The same. Hinge of the same: $\times 20$.
3. Soldiclla expausa (Jeftress), p. 871. Interior of right valve of specimen Ao. $7 \times 363 ; \times 16$.
4. Malletia obtusa (M. Sars) Märch, p.87t. Interior of left valve of a very joung specimen from station $2706 ; \times 20$.
5. Aximopsis corlata Verrill and Bush, p. 795. Interior of a left valve from station 2307: $\times 16$.
6. The same. Interior of a right valve from station $1092 ; \times 16$.
7. Malletia abyssormm Verill and Bush, p. 875. Interior of right valve of type speeimen No. 52159 ; $\times 12$.
8. Foldiella curfa Verrill amblush, p. 868. Interior of right valve of type specimen No. $38457 ; \times 20$.
9. Hyalopecten dilectus Verill and Bnsh, p. 836. A portion of the exterior of both valres of type specimen No. $52539 ; \times \delta$.

    2 The true IIyalopecten fragilis (Jefireys) wis taken at five stations betwean N. lat. $100^{\prime} 6^{\prime}$ W. long. $68^{\prime} 1^{\prime} 30^{\prime \prime}$, and N. lat. $3549^{\prime} 30^{\prime \prime}$, W. long. $74^{\circ} 34^{\prime} 45^{\prime \prime}$, in 578 to 1,525 fathoms, 1883-1886.

[^12]:    ${ }^{1}$ The two West Indian species described by Mr. Dall as Macrodon asperula and M. sagrinata, shonld, perhaps, form a separate genus, "haracterized by the few very ohlique, sublamellar, posterior terth and serral smaller, uearly transverse anterior ones. It may be designated as Bentharea, with Bentharea asperula as the type.

    These are elosely related to one of the Eocene fossil species (Irca adrersidentata), which leshayes placed in his gronp of "Cucullaires,' but later writers (Comrad, 1869, Fischer, and others) have taken his first species (heterodonta) of that gronp as the type of the gemus "Cucnllaria." which differs in baving the anterior as well as the posterior teeth long and lamelliform; hence we wonld associate Tertiary species like Benthurea ulversidentata with the living deop-water forms.

[^13]:    An alostract of the portion of this artirle relating to these families was published in thu American Jumrnal of Science, IlI, ए. 5l, January, 1897.
